INTRODUCTION

1

A survey of the finite simple groups

1. Prelimaries

The theory of groups is the theory of the different possible kinds of symmetry, and as such finds applications throughout mathematics and the sciences whenever symmetrical objects or theories are being discussed. We originally conceived this ATLAS as a work whose aim would be to convey every interesting fact about every interesting finite group. This, of course, was a tall order, only partly fulfilled by the present volume!

The most interesting groups are the simple groups, and perhaps the most impressive result of finite group theory is the recent complete classification of finite simple groups. This volume tabulates, for various finite simple groups G, the following information:

(i) the order of G, and the orders of its Schur multiplier and outer automorphism group;

(ii) various 'constructions' for G, or for concepts closely associated with G;

(iii) information about the subgroups of G and of its automorphism groups (often the complete list of maximal subgroups);

(iv) a 'compound character table' from which it is easy to read off the ordinary character table of G and those of various closely related groups.

Some of the terminology used here will be defined in later sections of this introduction. In general, we expect the reader to be familiar with the basic concepts of group theory and representation theory. The main aim of our definitions is to introduce the notation used later in the ATLAS, which is sometimes idiosyncratic.

According to the classification theorem, the finite simple groups fall into certain infinite families, with 26 extremely interesting exceptions called the *sporadic groups*. Many of the early terms in the infinite families display intriguing special behaviour. Within each family, we have continued until the groups became either too big or too boring, and have tried hard to include any group that had a property or properties not explained by its membership within that family. In doubtful cases, our rule was to *think how far the reasonable person would go, and then go a step further.* For the smaller families, this has had the effect that the last group included gives a very good idea of the structure of the typical element of the family. We have included all of the sporadic groups.

We have chosen to print the particular information described above partly for its obvious utility, and partly because we could manage to obtain a reasonably uniform coverage. Our first priority was to print the ordinary character table, which is beyond doubt the most compendious way of conveying information about a group to the skilled reader. Moreover, the computation of character tables is almost routine for groups of moderate size, while for several notorious groups of immoderate size it has been achieved after heroic efforts.

The complete list of maximal subgroups is very useful in internal investigations of the group, mainly because it reduces the difficult problem of deciding what group certain elements generate to the mere enumeration of cases. It is considerably harder to find all maximal subgroups than to compute the character table, but the answers are now known for a surprisingly large number of groups, and useful partial information is often available for other cases.

The Schur multipliers and outer automorphism groups of all finite simple groups are now known. (It should be noted that the computation of multipliers is delicate, and there have been several amendments to previously published lists.) For most of the groups treated in the ATLAS we also give the character tables for the corresponding covering groups and extensions by automorphisms. The individual tables are easily read off from the handy 'compound character table' into which we have combined them.

The typical expert in this subject knows a vast number of isolated facts about particular groups, but finds it very hard to convey this rather formless information to the earnest student. We hope that such students will find that our 'constructions' answer some of their questions. Usually the object constructed is the simple group itself or a close relative, but we allow it to be *any* concept connected with the group. Most of the interesting facts about our groups are fairly naturally described in these constructions, and we have not hesitated to stretch the 'constructions' format so as to swallow the odd counter-example.

We plead indulgence for the many defects in these rather hasty descriptions. The 'constructions' format arose almost by oversight at a fairly late stage in the preparation of our material, and we have not really had time to organize the information properly. However, we feel that they are already useful enough to be presented to the reader now, rather than postponed to a later volume.

In the rest of this introduction, we shall describe the finite simple groups and their classification, and then explain how to read the tables and text in the main body of the ATLAS.

2. The finite simple groups

Since finite simple groups are the main topic of this ATLAS, we had better describe them!

Combining the results of a large number of authors, we have:

The classification theorem for finite simple groups
The finite simple groups are to be found among:
- the cyclic groups of prime order
- the alternating groups of degree at least 5
- the Chevalley and twisted Chevalley groups, and the Tits group
- the 26 sporadic simple groups.

We briefly describe these classes. More detailed descriptions appear in the subsequent sections of this introduction, and in the ATLAS entries for the individual groups.

The cyclic groups of prime order are the only abelian (commutative) simple groups. There are so many ways in which these groups behave differently to the non-abelian simple groups that the term 'simple group' is often tacitly understood to mean 'non-abelian simple group'.

The fact that the alternating groups of degree at least 5 are non-abelian simple groups has been known since Galois, and implies that generic algebraic equations of degree at least 5 are insoluble by radicals. In fact the true origin of finite group theory is Galois theory.

The Chevalley and twisted Chevalley groups generalize the familiar 'classical' groups (the linear, unitary, symplectic, and orthogonal groups), which are particular cases. There is a sense in which the vast majority of finite simple groups belong to this class. The Tits group, which might have been considered as a sporadic group, is a simple subgroup of index 2 in the twisted group ${}^2F_4(2)$. We shall describe all the Chevalley groups in later sections.

3. The sporadic groups

The sporadic simple groups may be roughly sorted as the *Mathieu groups*, the *Leech lattice groups*, Fischer's *3-transposition groups*, the further *Monster centralizers*, and the half-dozen *oddments*.

For about a hundred years, the only sporadic simple groups were the Mathieu groups M_{11}, M_{12}, M_{22}, M_{23}, M_{24}. These were described by Emil Mathieu in 1861 and 1873 as highly transitive permutation groups, the subscripts indicating the numbers of letters permuted. (It is interesting to note that Mathieu, in the early language of Galois theory, spoke of *highly transitive functions* of several letters, rather than *highly transitive groups*.) One of the first great exercises in representation theory was the computation by Frobenius of the character table of M_{24}. Frobenius also showed that all the Mathieu groups were subgroups of M_{24} (the containment of M_{12} in M_{24} was not known to Mathieu).

The group M_{24} is one of the most remarkable of all finite groups. Many properties of the larger sporadic groups reduce on examination to properties of M_{24}. This centenarian group can still startle us with its youthful acrobatics.

The automorphism group of the Leech lattice, modulo a centre of order 2, is the Conway group Co_1, and by stabilizing sublattices of dimensions 1 and 2 we obtain the other Conway groups Co_2, Co_3, the McLaughlin group M^cL, and the Higman–Sims group HS. The sporadic Suzuki group Suz, and the Hall–Janko group $HJ = J_2$, can also be obtained from the Leech lattice by enlarging the ring of definition. The Leech lattice is a 24-dimensional Euclidean lattice which is easily defined in terms of the Mathieu group M_{24}.

The Fischer groups Fi'_{24}, Fi_{23}, Fi_{22}, were discovered by B. Fischer in the course of his enumeration of *3-transposition groups* (groups generated by a conjugacy class of involutions whose pairwise products have orders at most 3). Fi_{22} and Fi_{23} are 3-transposition groups, and Fi'_{24} has index 2 in the 3-transposition group Fi_{24}. There is a set S of 24 transpositions in Fi_{24} such that the elements of Fi_{24} that fix S as a whole realize exactly the permutations of M_{24} on S.

The Monster group, or Friendly Giant, which was independently discovered by B. Fischer and R. Griess, is the largest of the sporadic groups, with order

$$8080\ 17424\ 79451\ 28758\ 86459\ 90496\ 17107\ 57005\ 75436\ 80000\ 00000$$
$$= 2^{46}.3^{20}.5^{9}.7^{6}.11^{2}.13^{3}.17.19.23.29.31.41.47.59.71.$$

It involves all the sporadic groups so far mentioned. Many of them can be described as the non-abelian composition factors in the centralizers of various elements of the Monster. The remaining sporadic groups that can be so obtained are

$M = F_1$: the Monster itself
$B = F_{2+}$: Fischer's 'Baby Monster'
$Th = F_{3|3}$: the Thompson group
$HN = F_{5+}$: the Harada–Norton group, and
$He = F_{7+}$: the Held group.

The subscript on our F symbol specifies the relevant Monster element. In the same notation, we have $Co_1 = F_{2-}$, $Fi'_{24} = F_{3+}$. It hardly needs to be said that the Mathieu group M_{24} plays a vital role in the structure of the Monster.

The groups we referred to as the oddments are the remaining groups J_1, J_3, J_4 discovered by Janko, and those groups Ru, $O'N$, Ly discovered by Rudvalis, O'Nan, and Lyons. These were originally found in a variety of ways, but are probably now best constructed via matrix groups over finite fields. We

Table 1. The sporadic groups

Group	Order	Investigators	M	A
M_{11}	$2^4.3^2.5.11$	Mathieu	1	1

J_3	$2^7.3^5.5.17.19$	Janko/Higman, McKay	3	2
Ly	$2^8.3^7.5^6.7.11.31.37.67$	Lyons/Sims	1	1
Ru	$2^{14}.3^3.5^3.7.13.29$	Rudvalis/Conway, Wales	2	1
J_4	$2^{21}.3^3.5.7.11^3.23.29.31.37.43$	Janko/Norton, Parker, Benson, Conway, Thackray	1	1

give a brief table of the appropriate dimensions and fields:

group:	J_1	J_3	J_4	Ru	$O'N$	Ly
dimension:	7	9	112	28	45	111
field:	$\mathbb{F}_{11}$	$\mathbb{F}_4$	$\mathbb{F}_2$	$\mathbb{F}_2$	$\mathbb{F}_7$	$\mathbb{F}_5$

The 112-dimensional matrices for J_4 are rather complicated, but explicit matrices for the other five cases can be found in the appropriate 'constructions' sections of this ATLAS. The construction for J_4 makes heavy use of the Mathieu group M_{24}, while those for the O'Nan and Lyons groups involve M_{11}. The indicated representation of the Rudvalis group lifts to a complex representation of its double cover.

It has often happened that a sporadic group was predicted to exist some time before its construction, in sufficient detail to give its order, various local subgroups, and sometimes the character table. In such cases we have separated names by a slash in Table 1. Those who were mainly concerned with the prediction appear before the slash; those mainly concerned with the construction after it. Elsewhere in the ATLAS, we usually name the group after its predictor(s) only, in order to avoid a multiplicity of names, and we recommend this practice. The columns headed 'M' and 'A' give the orders of the Schur multiplier and outer automorphism group, which are both cyclic for each sporadic group. For the simple alternating groups ($n \geqslant 5$) we have $M=2$ (see page 236) except that A_6 and A_7 have $M=6$, and $A=2$ except that A_6 has $A=2^2$.

4. Finite fields

The description of the classical groups, and of the Chevalley and twisted Chevalley groups that generalize them, involves heavy use of the properties of finite fields. We summarize the main facts here.

The order of any finite field is a prime power, and for each prime power q there is up to isomorphism just one such field, which we call $\mathbb{F}_q$. The existence of these fields was established by Galois, and their uniqueness for each possible order by Moore. These fields are often referred to as Galois fields, and Dickson's notation $GF(q)$ is often used for $\mathbb{F}_q$.

If p is prime, the field $\mathbb{F}_p$ is just $\mathbb{Z}/p\mathbb{Z}$, the integers taken modulo p, while for $q=p^f$, the field $\mathbb{F}_q$ may be constructed from $\mathbb{F}_p$ by adjoining a root of any irreducible equation of degree f over $\mathbb{F}_p$. It may also be defined non-constructively as the set of solutions of $x^q=x$ in the algebraic closure of $\mathbb{F}_p$.

Since $\mathbb{F}_q$ is a vector space of dimension f over $\mathbb{F}_p$, its additive group is the direct sum of f cyclic groups of order p. The multiplicative group is cyclic of order $q-1$, and a generator for this group is called a *primitive root* for $\mathbb{F}_q$. There are exactly $\phi(q-1)$ primitive roots, where $\phi(n)$ is Euler's totient function. Although primitive roots are easily found by inspection in any particular case, there is no simple formula which gives a primitive root in $\mathbb{F}_q$ for an arbitrary given q.

The automorphism group of $\mathbb{F}_q$ is cyclic of order f, and consists of the maps $x \to x^r$ $(r=1, p, p^2, \ldots, p^{f-1})$, which are called the *Frobenius maps*. The subfields of $\mathbb{F}_q$ are those $\mathbb{F}_r$ for which q is a power of r, and each subfield is the fixed field of the corresponding Frobenius map. If $q=r^s$, then the characteristic polynomial over $\mathbb{F}_r$ of an element x of $\mathbb{F}_q$ is

$$(t-x)(t-x^r)\ldots(t-x^{r^{s-1}}),$$

The coefficients of this polynomial lie in $\mathbb{F}_r$. In particular, the *trace* and *norm* functions from $\mathbb{F}_q$ to $\mathbb{F}_r$ are defined by

$$Tr_{\mathbb{F}_q \to \mathbb{F}_r}(x) = x + x^r + x^{r^2} + \ldots + x^{r^{s-1}}$$
$$N_{\mathbb{F}_q \to \mathbb{F}_r}(x) = x \,.\, x^r \,.\, x^{r^2} \,.\ldots.\, x^{r^{s-1}} = x^{(r^s-1)/(r-1)}.$$

Any linear function from $\mathbb{F}_q$ to $\mathbb{F}_r$ can be written as $Tr_{\mathbb{F}_q \to \mathbb{F}_r}(kx)$ for a unique k in $\mathbb{F}_q$.

2

The classical groups

The *Linear, Unitary, Symplectic,* and *Orthogonal* groups have been collectively known as 'The classical groups' since the publication of Hermann Weyl's famous book of that name, which discussed them over the real and complex fields. Most of their theory has been generalized to the other Chevalley and twisted Chevalley groups. However, the classical definitions require little technical knowledge, lead readily to invariant treatments of the groups, and provide many techniques for easy calculations inside them. In this ATLAS we take a severely classical viewpoint, for the most part. Later in this introduction, however, we shall quickly describe the larger class of groups, and the present section contains some forward references.

1. The groups $GL_n(q)$, $SL_n(q)$, $PGL_n(q)$, and $PSL_n(q) = L_n(q)$

The *general linear group* $GL_n(q)$ consists of all the $n \times n$ matrices with entries in $\mathbb{F}_q$ that have non-zero determinant. Equivalently it is the group of all linear automorphisms of an n-dimensional vector space over $\mathbb{F}_q$. The *special linear group* $SL_n(q)$ is the subgroup of all matrices of determinant 1. The *projective general linear group* $PGL_n(q)$ and *projective special linear group* $PSL_n(q)$ are the groups obtained from $GL_n(q)$ and $SL_n(q)$ on factoring by the scalar matrices contained in those groups.

For $n \geqslant 2$ the group $PSL_n(q)$ is simple except for $PSL_2(2) = S_3$ and $PSL_2(3) = A_4$, and we therefore also call it $L_n(q)$, in conformity with Artin's convention in which single-letter names are used for groups that are 'generally' simple.

The orders of the above groups are given by the formulae

$$|GL_n(q)| = (q-1)N, \qquad |SL_n(q)| = |PGL_n(q)| = N,$$

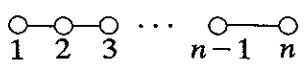
$$|PSL_n(q)| = |L_n(q)| = \frac{N}{d},$$

where

$$N = q^{\frac{1}{2}n(n-1)}(q^n-1)(q^{n-1}-1)\ldots(q^2-1),$$

and $d = (q-1, n)$.

$L_{n+1}(q)$ is the adjoint Chevalley group $A_n(q)$, with Dynkin diagram



(n nodes).

The maximal parabolic subgroup correlated with the node labelled k in the diagram corresponds to the stabilizer of a k-dimensional vector subspace.

2. The groups $GU_n(q)$, $SU_n(q)$, $PGU_n(q)$, and $PSU_n(q) = U_n(q)$

Let V be a vector space over $\mathbb{F}_{q^2}$. Then a function $f(x, y)$ which is defined for all x, y in V and takes values in $\mathbb{F}_{q^2}$ is called a *conjugate-symmetric sesquilinear form* if it satisfies

$$f(\lambda_1 x_1 + \lambda_2 x_2, y) = \lambda_1 f(x_1, y) + \lambda_2 f(x_2, y)$$

(linearity in x), and

$$f(y, x) = \overline{f(x, y)}$$

(conjugate-symmetry), where $x \to \bar{x} = x^q$ is the automorphism of $\mathbb{F}_{q^2}$ whose fixed field is $\mathbb{F}_q$. Such a form is necessarily *semilinear in* y, that is

$$f(x, \lambda_1 y_1 + \lambda_2 y_2) = \overline{\lambda_1} f(x, y_1) + \overline{\lambda_2} f(x, y_2).$$

It is called *singular* if there is some $x_0 \neq 0$ such that $f(x_0, y) = 0$ for all y. The *kernel* is the set of all such x_0. The *nullity* and *rank* are the dimension and codimension of the kernel.

A *Hermitian form* $F(x)$ is any function of the shape $f(x, x)$, where $f(x, y)$ is a conjugate-symmetric sesquilinear form. Since either of the forms F and f determines the other uniquely, it is customary to transfer the application of adjectives freely from one to the other. Thus $F(x) = f(x, x)$ is termed non-singular if and only if $f(x, y)$ is non-singular. Coordinates can always be chosen so that a given non-singular Hermitian form becomes

$$x_1\overline{x_1} + x_2\overline{x_2} + \ldots + x_n\overline{x_n}.$$

The *general unitary group* $GU_n(q)$ is the subgroup of all elements of $GL(q^2)$ that fix a given non-singular Hermitian form, or, equivalently, that fix the corresponding non-singular conjugate-symmetric sesquilinear form. If the forms are chosen to be the canonical one above, then a matrix U belongs to $GU_n(q)$ (is *unitary*) just if $U^{-1} = \bar{U}^t$, the matrix obtained by replacing the entries of U^t by their qth powers.

The determinant of a unitary matrix is necessarily a $(q+1)$st root of unity. The *special unitary group* $SU_n(q)$ is the subgroup of unitary matrices of determinant 1. The *projective general unitary group* $PGU_n(q)$ and *projective special unitary group* $PSU_n(q)$ are the groups obtained from $GU_n(q)$ and $SU_n(q)$ on factoring these groups by the scalar matrices they contain.

For $n \geqslant 2$, the group $PSU_n(q)$ is simple with the exceptions

$$PSU_2(2) = S_3, \qquad PSU_2(3) = A_4, \qquad PSU_3(2) = 3^2 : Q_8,$$

and so we also give it the simpler name $U_n(q)$. We have $U_2(q) = L_2(q)$.

The orders of the above groups are given by

$$|GU_n(q)| = (q+1)N, \qquad |SU_n(q)| = |PGU_n(q)| = N,$$

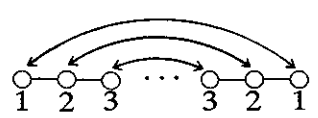
$$|PSU_n(q)| = |U_n(q)| = \frac{N}{d},$$

where

$$N = q^{\frac{1}{2}n(n-1)}(q^n - (-1)^n)(q^{n-1} - (-1)^{n-1})\ldots(q^3+1)(q^2-1),$$

and $d = (q+1, n)$.

$U_{n+1}(q)$ is the twisted Chevalley group ${}^2A_n(q)$, with the Dynkin diagram and twisting automorphism indicated:



(n nodes).

The maximal parabolic subgroup correlated with the orbit of nodes labelled k in the diagram corresponds to the stabilizer of a k-dimensional totally isotropic subspace (i.e. a space on which $F(x)$ or equivalently $f(x, y)$ is identically zero).

3. The groups $Sp_n(q)$ and $PSp_n(q) = S_n(q)$

An *alternating bilinear form* (or *symplectic form*) on a vector space V over $\mathbb{F}_q$ is a function $f(x, y)$ defined for all x, y in V and taking values in $\mathbb{F}_q$, which satisfies

$$f(\lambda_1 x_1 + \lambda_2 x_2, y) = \lambda_1 f(x_1, y) + \lambda_2 f(x_2, y)$$

(linearity in x), and also

$$f(y, x) = -f(x, y) \quad \text{and} \quad f(x, x) = 0$$

(skew-symmetry and alternation). It is automatically linear in y also (and so *bilinear*).

The *kernel* of such a form is the subspace of x such that $f(x, y) = 0$ for all y, and the *nullity* and *rank* of f are the dimension and codimension of its kernel. A form is called non-singular if its nullity is zero. The rank of a symplectic form is necessarily an even number, say $2m$, and coordinates can be chosen so that the form has the shape

$$x_1y_{m+1} + x_2y_{m+2} + \ldots + x_my_{2m} - x_{m+1}y_1 - x_{m+2}y_2 - \ldots - x_{2m}y_m.$$

For an even number $n = 2m$, the *symplectic group* $Sp_n(q)$ is defined as the group of all elements of $GL_n(q)$ that preserve a given non-singular symplectic form $f(x, y)$. Any such matrix necessarily has determinant 1, so that the 'general' and 'special' symplectic groups coincide. The *projective symplectic group* $PSp_n(q)$ is obtained from $Sp_n(q)$ on factoring it by the subgroup of scalar matrices it contains (which has order at most 2). For $2m \geqslant 2$, $PSp_{2m}(q)$ is simple with the exceptions

$$PSp_2(2) = S_3, \qquad PSp_2(3) = A_4, \qquad PSp_4(2) = S_6$$

and so we also call it $S_{2m}(q)$. We have $S_2(q) = L_2(q)$.

If A, B, C, D are $m \times m$ matrices, then $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ belongs to the symplectic group for the canonical symplectic form above just if

$$A^tC - C^tA = 0, \qquad A^tD - C^tB = I, \qquad B^tD - D^tB = 0,$$

where M^t denotes a transposed matrix.

The orders of the above groups are given by

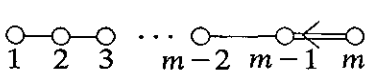
$$|Sp_{2m}(q)| = N, \qquad |PSp_{2m}(q)| = |S_{2m}(q)| = \frac{N}{d},$$

where

$$N = q^{m^2}(q^{2m} - 1)(q^{2m-2} - 1) \ldots (q^2 - 1)$$

and $d = (q - 1, 2)$.

$S_{2m}(q)$ is the adjoint Chevalley group $C_m(q)$ with Dynkin diagram



(m nodes).

The maximal parabolic group correlated with the node labelled k corresponds to the stabilizer of a k-dimensional totally isotropic subspace (that is, a space on which $f(x, y)$ is identically zero).

4. The groups $GO_n(q)$, $SO_n(q)$, $PGO_n(q)$, $PSO_n(q)$, and $O_n(q)$

A *symmetric bilinear form* on a space V over $\mathbb{F}_q$ is a function $f(x, y)$ defined for all x, y in V and taking values in $\mathbb{F}_q$ which satisfies

$$f(\lambda_1x_1 + \lambda_2x_2, y) = \lambda_1 f(x_1, y) + \lambda_2 f(x_2, y)$$

(linearity in x), and also

$$f(y, x) = f(x, y)$$

(symmetry). It is then automatically linear in y. A *quadratic form* on V is a function $F(x)$ defined for x in V and taking values in $\mathbb{F}_q$, for which we have

$$F(\lambda x + \mu y) = \lambda^2 F(x) + \lambda\mu f(x, y) + \mu^2 F(y)$$

for some symmetric bilinear form $f(x, y)$.

The *kernel of* f is the subspace of all x such that $f(x, y) = 0$ for all y, and the *kernel of* F is the set of all x in the kernel of f for which also $F(x) = 0$.

When the characteristic is not 2, F and f uniquely determine each other, so that the two kernels coincide. The literature contains a bewildering variety of terminology adapted to describe the more complicated situations that can hold in characteristic 2. This can be greatly simplified by using only a few standard terms (rank, nullity, non-singular, isotropic), but always being careful to state to which of f and F they apply.

Thus we define the *nullity* and *rank* of either f or F to be the dimension and codimension of its kernel, and say that f or F is *non-singular* just when its nullity is zero. A subspace is said to be (*totally*) *isotropic for* f if $f(x, y)$ vanishes for all x, y in that subspace, and (*totally*) *isotropic for* F if $F(x)$ vanishes for all x in the subspace. When the characteristic is not 2 our adjectives can be freely transferred between f and F.

The *Witt index* of a quadratic form F is the greatest dimension of any totally isotropic subspace for F. It turns out that if two non-singular quadratic forms on the same space over $\mathbb{F}_q$ have the same Witt index, then they are equivalent to scalar multiples of each other. The *Witt defect* is obtained by subtracting the Witt index from its largest possible value, $[\frac{1}{2}n]$. For a non-singular form over a finite field the Witt defect is 0 or 1.

The *general orthogonal group* $GO_n(q, F)$ is the subgroup of all elements of $GL_n(q)$ that fix the particular non-singular quadratic form F. The determinant of such an element is necessarily ± 1, and the *special orthogonal group* $SO_n(q, F)$ is the subgroup of all elements with determinant 1. The *projective general orthogonal group* $PGO_n(q, F)$ and *projective special orthogonal group* $PSO_n(q, F)$ are the groups obtained from $GO_n(q, F)$ and $SO_n(q, F)$ on factoring them by the groups of scalar matrices they contain.

In general $PSO_n(q, F)$ is *not* simple. However, it has a certain subgroup, specified precisely later, that is simple with finitely many exceptions when $n \geqslant 5$. This subgroup, which is always of index at most 2 in $PSO_n(q, F)$, we call $O_n(q, F)$.

When $n = 2m + 1$ is odd, all non-singular quadratic forms on a space of dimension n over $\mathbb{F}_q$ have Witt index m and are equivalent up to scalar factors. When $n = 2m$ is even, there are up to equivalence just two types of quadratic form, the *plus type*, with Witt index m, and the *minus type*, with Witt index $m - 1$. (These statements make use of the finiteness of $\mathbb{F}_q$.) Accordingly, we obtain only the following distinct families of groups:

When n is odd $GO_n(q)$, $SO_n(q)$, $PGO_n(q)$, $PSO_n(q)$, $O_n(q)$, being the values of $GO_n(q, F)$ (etc.) for any non-singular F.

When n is even $GO_n^\varepsilon(q)$, $SO_n^\varepsilon(q)$, $PGO_n^\varepsilon(q)$, $PSO_n^\varepsilon(q)$, $O_n^\varepsilon(q)$ for either sign $\varepsilon = +$ or $-$, being the values of $GO_n(q, F)$ (etc.) for a form F of plus type or minus type respectively.

We now turn to the problem of determining the generally simple group $O_n(q)$ or $O_n^\varepsilon(q)$. This can be defined in terms of the invariant called the *spinor norm*, when q is odd, or in terms of the *quasideterminant*, when q is even. We define these below, supposing $n \geqslant 3$ (the groups are boring for $n \leqslant 2$).

A vector r in V for which $F(r) \neq 0$ gives rise to certain elements of $GO_n(q, F)$ called *reflections*, defined by the formula

$$x \to x - \frac{f(x, r)}{F(r)} \,.\, r.$$

We shall now define a group $\Omega_n^\varepsilon(q)$ of index 1 or 2 in $SO_n^\varepsilon(q)$. The image $P\Omega_n^\varepsilon(q)$ of this group in $PSO_n^\varepsilon(q)$ is the group we call $O_n^\varepsilon(q)$, which is usually simple. The Ω, $P\Omega$ notation was introduced by Dieudonné, who defined $\Omega_n^\varepsilon(q)$ to be the commutator subgroup of $SO_n^\varepsilon(q)$, but we have changed the definition so as to obtain the 'correct' groups (in the Chevalley sense) for small n. For $n \geqslant 5$ our groups agree with Dieudonné's.

When q is odd, $\Omega_n^\varepsilon(q)$ is defined to be the set of all those g in $SO_n^\varepsilon(q)$ for which, when g is expressed in any way as the product of reflections in vectors $r_1, r_2, \ldots, r_t$, we have

$$F(r_1) \,.\, F(r_2) \,.\, \ldots \,.\, F(r_t) \quad \text{a square in } \mathbb{F}_q.$$

The function just defined is called the *spinor norm* of g, and takes values in $\mathbb{F}_q^*/(\mathbb{F}_q^*)^2$, where $\mathbb{F}_q^*$ is the multiplicative group of $\mathbb{F}_q$. Then $\Omega_n^\varepsilon(q)$ has index 2 in $SO_n^\varepsilon(q)$. It contains the scalar matrix -1 just when $n = 2m$ is even and $(4, q^m - \varepsilon) = 4$.

When q is even, then if $n = 2m + 1$ is odd, $SO_n(q) = GO_n(q)$ is isomorphic to the (usually simple) symplectic group $Sp_{2m}(q)$, and we define $\Omega_n(q) = SO_n(q)$. To obtain the isomorphism, observe that the associated symmetric bilinear form f has a one-dimensional kernel, and yields a non-singular symplectic form on $V/ker(f)$.

For arbitrary q, and $n=2m$ even, we define the *quasideterminant* of an element to be $(-1)^k$, where k is the dimension of its fixed space. Then for q odd this homomorphism agrees with the determinant, and for q even we define Ω_n^ε to be its kernel. The quasideterminant can also be written as $(-1)^D$, where D is a polynomial invariant called the Dickson invariant, taking values in $\mathbb{F}_2$.

An alternative definition of the quasideterminant is available. When $\varepsilon=+$ there are two families of maximal isotropic subspaces for F, two spaces being in the same family just if the codimension of their intersection in either of them is even. Then the quasideterminant of an element is 1 or -1 according as it preserves each family or interchanges the two families. When $\varepsilon=-$, the maximal isotropic spaces defined over $\mathbb{F}_q$ have dimension $m-1$, but if we extend the field to $\mathbb{F}_{q^2}$, we obtain two families of m-dimensional isotropic spaces and can use the same definition.

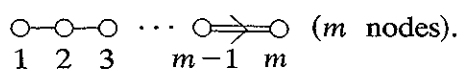
When $n=2m+1$ is odd, the groups have orders

$$|GO_n(q)|=dN, \qquad |SO_n(q)|=|PGO_n(q)|=|PSO_n(q)|=N,$$
$$|\Omega_n(q)|=|P\Omega_n(q)|=|O_n(q)|=N/d,$$

where

$$N=q^{m^2}(q^{2m}-1)(q^{2m-2}-1)\dots(q^2-1)$$

and $d=(2,q-1)$. $O_{2m+1}(q)$ is the adjoint Chevalley group $B_m(q)$, with Dynkin diagram



(m nodes).

The maximal parabolic subgroup correlated with the node labelled k corresponds to the stabilizer of an isotropic k-space for F.

When $n=2m$ is even, the groups have orders

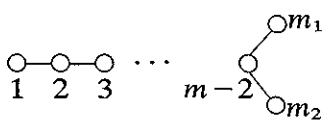
$$|GO_n^\varepsilon(q)|=2N, \qquad |SO_n^\varepsilon(q)|=|PGO_n^\varepsilon(q)|=2N/e,$$
$$|PSO_n^\varepsilon(q)|=2N/e^2, \qquad |\Omega_n^\varepsilon(q)|=N/e,$$
$$|P\Omega_n^\varepsilon(q)|=|O_n(q)|=N/d,$$

where

$$N=q^{m(m-1)}(q^m-\varepsilon)(q^{2m-2}-1)(q^{2m-4}-1)\dots(q^2-1)$$

and $d=(4,q^m-\varepsilon)$, $e=(2,q^m-\varepsilon)$.

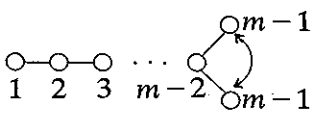
$O_{2m}^+(q)$ is the adjoint Chevalley group $D_m(q)$, with Dynkin diagram



(m nodes).

The maximal parabolic subgroup correlated with the node labelled $k\leqslant m-2$ corresponds to the stabilizer of an isotropic k-space for F. Those correlated with the nodes labelled m_1 and m_2 correspond to stabilizers of members of the two families of isotropic m-spaces for F.

$O_{2m}^-(q)$ is the twisted Chevalley group ${}^2D_m(q)$, with the Dynkin diagram and twisting automorphism



(m nodes).

The maximal parabolic subgroup correlated with the orbit of nodes labelled $k\leqslant m-1$ corresponds to the stabilizer of an isotropic k-space for F.

For $n\leqslant 6$, the orthogonal groups are isomorphic to other classical groups, as follows:

$$O_3(q)=L_2(q), \qquad O_4^+(q)=L_2(q)\times L_2(q), \qquad O_4^-(q)=L_2(q^2),$$
$$O_5(q)=S_4(q), \qquad O_6^+(q)=L_4(q), \qquad O_6^-(q)=U_4(q).$$

The group $O_n(q)$ is simple for $n\geqslant 5$, with the single exception that $O_5(2)=S_4(2)$ is isomorphic to the symmetric group S_6.

5. Classification of points and hyperplanes in orthogonal spaces

Let V be a space equipped with a non-singular quadratic form F. Then for fields of odd characteristic many authors classify the vectors of V into three classes according as

$F(v)=0$,
$F(v)$ a non-zero square,
$F(v)$ a non-square,

since these correspond exactly to the three orbits of projective points under the orthogonal group of F.

In this ATLAS we prefer a different way of making these distinctions, which is independent of the choice of any particular scalar multiple of the quadratic form F, and which does the correct thing in characteristic 2. We say that a subspace H of even dimension on which F is non-singular is of *plus type* or *minus type* according to the type of F when restricted to H, and if H is the hyperplane perpendicular to a vector v, we apply the same adjectives to v. Thus our version of the above classification is

v *isotropic* (or *null*),
v of *plus type*,
v of *minus type*.

Table 2. Structures of classical groups

d	$GL_n(q)$	$PGL_n(q)$	$SL_n(q)$	$PSL_n(q)=L_n(q)$

6. The Clifford algebra and the spin group

The *Clifford algebra* of F is the associative algebra generated by the vectors of V with the relations $x^2 = F(x)$, which imply $xy + yx = f(x, y)$. If V has basis $e_1, \ldots, e_n$, then the Clifford algebra is 2^n-dimensional, with basis consisting of the formal products

$$e_{i_1} e_{i_2} \ldots e_{i_k} \quad (i_1 < i_2 < i_3 < \ldots < i_k,\ k \leq n).$$

The vectors r with $F(r) \neq 0$ generate a subgroup of the Clifford algebra which is a central extension of the orthogonal group, the vector r in the Clifford algebra mapping to the negative of the reflection in r. When the ground field has characteristic $\neq 2$, this remark can be used to construct a proper double cover of the orthogonal group, called the *spin group*.

7. Structure tables for the classical groups

Table 2 describes the structure of all the groups mentioned, in terms of the usually simple group G, which is the appropriate one of $L_n(q)$, $U_n(q)$, $S_n(q)$, $O_n(q)$.

8. Other notations for the simple groups

There are many minor variations such as $L_n(\mathbb{F}_q)$ or $L(n, q)$ for $L_n(q)$ which should give little trouble. However, the reader should be aware that although the 'smallest field' convention which we employ in this ATLAS is rapidly gaining ground amongst group theorists, there are still many people who write $U_n(q^2)$ or $U(n, q^2)$ for what we call $U_n(q)$. Artin's 'single letter for simple group' convention is not universally adopted, so that many authors would use $U_n(q)$ and $O_n(q)$ for what we call $GU_n(q)$ and $GO_n(q)$. The notations $E_2(q)$ and $E_4(q)$ have sometimes been used for $G_2(q)$ and $F_4(q)$.

Dickson's work has had a profound influence on group theory, and his notations still have some currency, but are rapidly becoming obsolete. Here is a brief dictionary:

$$\begin{aligned}
&\text{(Linear fractional) } LF(n, q) = L_n(q)\\
&\text{(Hyperorthogonal) } HO(n, q^2) = U_n(q)\\
&\text{(Abelian linear) } A(2m, q) = S_{2m}(q)\\
&\text{(First orthogonal)} \begin{cases} FO(2m+1, q) = O_{2m+1}(q) \\ FO(2m, q) = O^{\varepsilon}_{2m}(q) \end{cases} \text{where } \varepsilon = \pm 1,\\
&\text{(Second orthogonal) } SO(2m, q) = O^{-\varepsilon}_{2m}(q) \quad q^m \equiv \varepsilon \text{ modulo } 4.\\
&\text{(First hypoabelian) } FH(2m, q) = O^{+}_{2m}(q)\\
&\text{(Second hypoabelian) } SH(2m, q) = O^{-}_{2m}(q)
\end{aligned}$$

Dickson's first orthogonal group is that associated with the quadratic form $x_1^2 + x_2^2 + \ldots + x_n^2$. His orthogonal groups are defined only for odd q, and his hypoabelian groups only for even q. He uses the notation $GLH(n, q)$ (General Linear Homogeneous group) for $GL_n(q)$.

3

The Chevalley and twisted Chevalley groups

1. The untwisted groups

The Chevalley and twisted Chevalley groups include and neatly generalize the classical families of linear, unitary, symplectic, and orthogonal groups.

In the entries for individual groups in the ATLAS, we have preferred to avoid the Chevalley notation, since it requires considerable technical knowledge, and since most of the groups we discuss also have classical definitions. The classical descriptions, when available, permit easy calculation, and lead readily to the desired facts about subgroups, etc.

However, for a full understanding of the entire set of finite simple groups, the Chevalley theory is unsurpassed. In particular the isomorphisms such as $L_4(q) = O_6^+(q)$ between different classical groups of the same characteristic become evident. The full Chevalley theory is beyond the scope of this ATLAS, but in the next few pages we give a brief description for those already acquainted with some of the terminology of Lie groups and Lie algebras. We reject any reproach for the incompleteness of this treatment. It is intended merely to get us to the point where we can list all the groups, and the isomorphisms among them, and also ~~to~~ specify their Schur multipliers and outer automorphism groups.

In 1955 Chevalley discovered a uniform way to define bases for the complex simple Lie algebras in which all their structure constants were rational integers. It follows that analogues of these Lie algebras and the corresponding Lie groups can be defined over arbitrary fields. The resulting groups are now known as the *adjoint Chevalley groups*. Over finite fields, these groups are finite groups which are simple in almost all cases. The definition also yields certain covering groups, which are termed the *universal Chevalley groups*. If a given finite simple group can be expressed as an adjoint Chevalley group, then in all but finitely many cases its abstract universal cover is the corresponding universal Chevalley group.

In the standard notation, the complex Lie algebras are

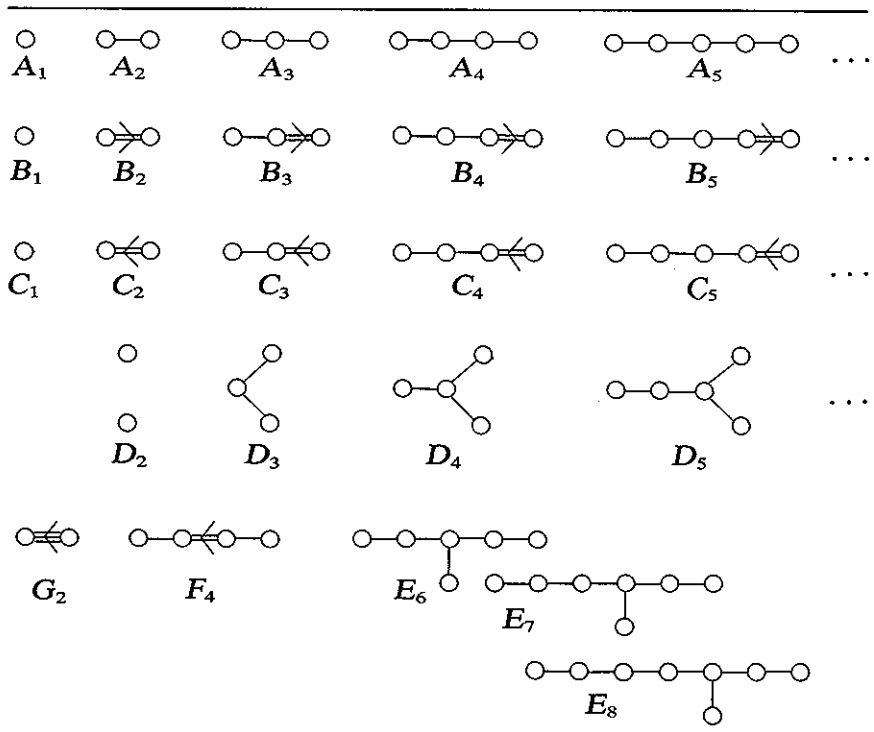
$$A_n \quad B_n \quad C_n \quad D_n \quad G_2 \quad F_4 \quad E_6 \quad E_7 \quad E_8$$

where to avoid repetitions we may demand that $n \geq 1, 2, 3, 4$ for A_n, B_n, C_n, D_n respectively. The corresponding adjoint Chevalley groups are denoted by

$$A_n(q),\ B_n(q),\ C_n(q),\ D_n(q),\ G_2(q),\ F_4(q),\ E_6(q),\ E_7(q),\ E_8(q).$$

The corresponding *Dynkin diagrams*, which specify the structure of the fundamental roots, appear in Table 3. In the cases when a p-fold branch appears ($p = 2$ or 3), the arrowhead points from long roots to short ones, the ratio of lengths being $\sqrt{p}$. We have included the non-simple case $D_2 = A_1 \oplus A_1$, and the repetitions $A_1 = B_1 = C_1$, $B_2 = C_2$, $A_3 = D_3$, since these help in the understanding of the relations between various classical groups.

Table 3. Dynkin diagrams



2. The twisted groups

Steinberg showed that a modification of Chevalley's procedure could be made to yield still more finite groups, and in particular, the unitary groups.

Any symmetry of the Dynkin diagram (preserving the direction of the arrowhead, if any) yields an automorphism of the Lie group or its Chevalley analogues, called an *ordinary graph automorphism*. Let us suppose that α is such an automorphism, of order t, and call it the *twisting automorphism*. We now define the *twisted Chevalley group* ${}^tX_n(q, q^t)$ to be set of elements of $X_n(q^t)$ that are fixed by the quotient of the twisting automorphism and the field automorphism induced by the Frobenius map $x \to x^q$ of F_{q^t}.

The particular cases are

$$\begin{aligned} &{}^2A_n(q, q^2) = U_{n+1}(q), \quad (n \geq 2) \\ &{}^2D_n(q, q^2) = O_{2n}^-(q), \quad (n \geq 3) \\ &{}^3D_4(q, q^3), \\ &{}^2E_6(q, q^2), \end{aligned}$$

the last two families being discovered by Steinberg. We usually abbreviate ${}^tX_n(q, q^t)$ to ${}^tX_n(q)$.

A further modification yields the infinite families of simple groups discovered by Suzuki and Ree. If the Dynkin diagram of X_n has a p-fold edge ($p = 2, 3$), then over fields of characteristic p the Chevalley group is independent of the direction of the arrowhead on that edge. In other words, there is an isomorphism between $X_n(p^f)$ and $Y_n(p^f)$, where Y_n is the diagram obtained from X_n by reversing the direction of the arrowhead. Thus for example, $B_n(2^f) = C_n(2^f)$, or in classical notation $O_{2n+1}(2^f) = S_{2n}(2^f)$, as we have already seen.

In the three cases $B_2 = C_2$, G_2, F_4, the diagram has an automorphism reversing the direction of the p-fold edge, and so over fields of the appropriate characteristic p, the resulting Chevalley groups have a new type of graph automorphism, which we call an *extraordinary graph automorphism*, whose square is the field automorphism induced by the Frobenius map $x \to x^p$.

Now when $q = p^{2m+1}$ is an odd power of this p, the field automorphism induced by $x \to x^{p^{m+1}}$ has the same square, and the elements of $X_n(p^{2m+1})$ fixed by the quotient of these two automorphisms form a new type of twisted Chevalley group, called ${}^2X_n(*, p^{2m+1})$, and usually abbreviated to ${}^2X_n(p^{2m+1})$. The particular cases are

$${}^2B_2(*, 2^{2m+1}) = {}^2C_2(*, 2^{2m+1}), \text{ a } \textit{Suzuki group},$$
$${}^2G_2(*, 3^{2m+1}), \text{ a } \textit{Ree group} \text{ of characteristic 3},$$
$${}^2F_4(*, 2^{2m+1}), \text{ a } \textit{Ree group} \text{ of characteristic 2}.$$

These groups are often written

$$Sz(q), R_1(q), R_2(q),$$

where $q = p^{2m+1}$, but the subscripts 1 and 2 for the two types of Ree group can be omitted without risk of confusion.

It turns out that the first group in each of these families is not simple, but all the later ones are simple. The cases are

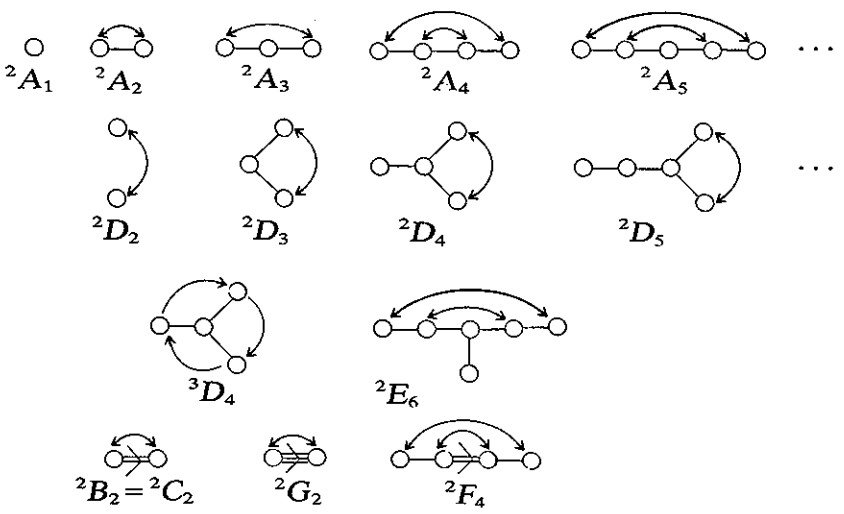
${}^2B_2(2) = 5:4$, the Frobenius group of order 20,

${}^2G_2(3) = L_2(8):3$, the extension of the simple group $L_2(8)$ of order 504 by its field automorphism,

${}^2F_4(2) = T.2$, where T is a simple group not appearing elsewhere in the classification of simple groups, called the *Tits group*.

Table 4 gives the Dynkin diagrams and twisting automorphisms for all the twisted groups. We remark that what we have called simply the twisted Chevalley groups are more fully called

Table 4. Diagrams and twisting automorphisms for twisted groups



the *adjoint* twisted Chevalley groups, and that, like the untwisted groups, they have certain multiple covers called the *universal twisted Chevalley groups*. We have included the untwisted group ${}^2A_1 = A_1$ in the table, and also the case ${}^2D_2$ obtained by twisting a disconnected diagram, and the repetition ${}^2A_3 = {}^2D_3$. The reason is again that these special cases illuminate relations between some classical groups.

3. Multipliers and automorphisms of Chevalley groups

The Schur multiplier has order de, and the outer automorphism group has order dfg, where the order of the base field is $q = p^f$ (p prime), and the numbers d, f, g are tabulated in Table 5. (An entry '2 if ...' means 1 if *not*.)

The Schur multiplier is the direct product of groups of orders d (the *diagonal multiplier*) and e (the *exceptional multiplier*). The diagonal multiplier extends the adjoint group to the corresponding universal Chevalley group. The exceptional multiplier is always a p-group (for the above p), and is trivial except in finitely many cases.

The outer automorphism group is a semidirect product (in this order) of groups of orders d (*diagonal automorphisms*), f (*field automorphisms*), and g (*graph automorphisms modulo field automorphisms*), except that for

$$B_2(2^f), G_2(3^f), F_4(2^f)$$

the (extraordinary) graph automorphism squares to the generating field automorphism. The groups of orders d, e, f, g are cyclic except that 3! indicates the symmetric group of degree 3, and orders written as powers indicate the corresponding direct powers of cyclic groups.

4. Orders of the Chevalley groups

In Table 6, the parameters have been chosen so as to avoid the 'generic' isomorphisms.
N is the order of the universal Chevalley group.
N/d is the order of the adjoint Chevalley group.

5. The simple groups enumerated

The exact list of finite simple groups is obtained from the union of

the list of Chevalley groups (Table 5)
the alternating groups A_n, for $n \geq 5$
the cyclic groups of prime order
the 26 sporadic groups, and finally
the Tits simple group $T = {}^2F_4(2)'$

by taking into account the exceptional isomorphisms below. Each of these isomorphisms is either between two of the above groups, or between one such group and a non-simple group. For the reader's convenience, we give both the Chevalley and classical notations.

The exceptional isomorphisms:

$A_1(2) = L_2(2) \cong S_3$	$B_2(2) = S_4(2) \cong S_6$
$A_1(3) = L_2(3) \cong A_4$	$G_2(2) \cong {}^2A_2(3).2 = U_3(3).2$
$A_1(4) = L_2(4) \cong A_5$	${}^2A_2(2) = U_3(2) \cong 3^2.Q_8$
$A_1(5) = L_2(5) \cong A_5$	${}^2A_3(2) = U_4(2) \cong B_2(3) = S_4(3)$
$A_1(7) = L_2(7) \cong A_2(2) = L_3(2)$	${}^2B_2(2) = Sz(2) \cong 5:4$
$A_1(9) = L_2(9) \cong A_6$	${}^2G_2(3) = R(3) \cong A_1(8).3 = L_2(8).3$
$A_3(2) = L_4(2) \cong A_8$	${}^2F_4(2) = R(2) \cong T.2.$

6. Parabolic subgroups

With every proper subset of the nodes of the Dynkin diagram there is associated a *parabolic subgroup*, which is in structure a p-group extended by the Chevalley group determined by the subdiagram on those nodes. (Here p, as always, denotes the characteristic of the ground field $\mathbb{F}_q$.) The *maximal parabolic subgroups* are those associated to the sets containing all but one of the nodes—we shall say that such a subgroup is *correlated* to the remaining node. According to the *Borel–Tits theorem* the maximal p-local subgroups of a Chevalley group are to be found among its maximal parabolic subgroups. These statements hold true for the twisted groups, provided we replace 'node' by 'orbit of nodes under the twisting automorphism'.

7. The fundamental representations

The ordinary representation theory of Chevalley groups, as recently developed by Deligne and Lusztig, is very complex, and the irreducible modular representations are not yet completely described. But certain important representations (not always irreducible) can be obtained from the representation theory of Lie groups.

The irreducible representations of a Lie group are completely classified, and can be written as 'polynomials' in certain *fundamental representations*, one for each node of the Dynkin diagram. The degrees of the representations for the various Lie groups X_n are given in Table 7. By change of field, we obtain the so-called fundamental representations of the universal Chevalley group $X_n(q)$, which are representations over the field $\mathbb{F}_q$ having the given degrees. In the classical cases these are fairly easily described geometrically—for example in $A_n(q) = L_{n+1}(q)$ the fundamental representation corresponding to the rth node is that of $SL_{n+1}(q)$ on the rth exterior power of the original vector space V.

Table 5. Automorphisms and multipliers of the Chevalley groups

Condition	Group	Definitions of d	f	g	Cases when $e \neq 1$
	$A_1(q)$	$(2, q-1)$	$q=p^f$	1	$A_1(4) \to 2$, $A_1(9) \to 3$

4

How to read this ATLAS: the 'constructions' sections

The typical ATLAS entry has four parts, giving:

1. the order of G, and its Schur multiplier and outer automorphism group;
2. various constructions for G, or related groups or concepts;
3. the maximal subgroups of G and its automorphic extensions;
4. the compound character table, from which the ordinary character tables for various extensions of G can be read off.

The parts are usually in this order, but the exigencies of pagination have occasionally forced us to put the character table first. For some large groups, we can only give partial information. Below, we discuss the type of information contained.

1. Order, multiplier, and outer automorphism group

Every reader of this ATLAS should be familiar with the notion of the *order* of a finite group! The set of all *automorphisms* (isomorphisms from G onto itself) of a given group G forms a group $Aut(G)$ called the *automorphism group* of G. Any element g of G yields a particular automorphism $x \to g^{-1}xg$ called *transformation* or *conjugation* by g, or the inner automorphism determined by g, and the set of all such automorphisms is a normal subgroup $Inn(G)$ of $Aut(G)$, the *inner automorphism group*. It is abstractly isomorphic to the quotient of G by its centre. The quotient group $Aut(G)/Inn(G) = Out(G)$ is the *outer automorphism group* of G.

A *central extension*, or *covering group*, of G is a group H with a central subgroup C whose quotient is G. It is called a *proper covering group* if C is contained in the commutator subgroup of H. The groups C that arise for proper covers of G are each of them quotients of a largest one, called the *Schur multiplier* (or *multiplicator*), Mult(G), of G. The corresponding central extension is only determined up to *isoclinism*, see Chapter 6, Section 7. However, for a perfect group G (and in particular for a simple G), we *do* have a unique *universal covering group*, of which any proper cover of G is a quotient, and for which C is the Schur multiplier of G.

The multiplier may be computed in the following way: Let G be defined by the relations

$$R_1(a_1, a_2, \ldots) = 1, \ldots, R_j(a_1, a_2, \ldots) = 1, \ldots$$

in generators $a_1, \ldots, a_i, \ldots$. Then the modified relations

$$R_j(a_1, \ldots) = z_j, \qquad a_i z_j = z_j a_i$$

define a group H which is a central extension of G by the subgroup

$$C = \langle z_1, z_2, \ldots \rangle$$

of H. Then the Schur multiplier of G is the intersection of C with the commutator subgroup of H. Moreover, if we factor H by a subgroup of C that is maximal subject to its not intersecting the commutator subgroup, we obtain one of the proper covers of G by its multiplier. The multiplier plays an important role in representation theory—see later sections.

2. Constructions

Under this heading, we give brief descriptions of various ways of constructing G, various closely related groups, or objects of which these groups are the automorphism groups. The style is telegraphic, and the reader must expect to fill in many details for himself. However, we have tried wherever possible to make the definitions so explicit that a sufficiently determined reader can completely recover the group or object from our description of it.

For the classical definitions, say of the unitary groups, we have been content to give merely the definition itself, and the structure of the various groups in terms of the simple group G, for example

$$GU_3(5) = 2 \times 3 \,.\, G \,.\, 3, \qquad PGU_3(5) = G \,.\, 3,$$
$$SU_3(5) = 3 \,.\, G, \qquad PSU_3(5) = U_3(5) = G.$$

The most interesting constructions, however, are those that relate the group to some special combinatorial object whose existence is not immediate from the classical definition; for example in the case of $U_3(5)$ the Hoffman–Singleton graph of 50 vertices, each joined to 7 others, whose automorphism group is $G \,.\, 2 = P\sum U_3(5)$. There is no reasonable analogue of this for the other unitary groups. In such cases, the thing we construct may be the combinatorial object, its automorphism group, or preferably both.

The combinatorial object is usually a set of some kind, and often a set of vectors in some space. In the simplest cases we have been able to give explicit names for all the members of this set, and also for all their automorphisms, but more usually we have only been able to specify a generating set of automorphisms. We have usually tried to make this generating set as large as we can, rather than as small as we can, since computations are then easier. Readers who want minimal systems of generators must look elsewhere!

In some large cases we have only been able to give a description of the relevant object rather than an explicit construction. We are pleased to report that in several cases where our description was originally of this kind we have managed, sometimes at the proof stage, to insert a more explicit construction. (The publishers of the ATLAS were not quite so pleased!)

In very complicated cases the work of the construction has been spread over several sections, each individually called a 'construction' because it constructs some portion of the final object. In this way we have even managed to fit a complete and explicit construction for the Monster onto a few ATLAS pages!

In the remainder of this chapter, we briefly describe some notations and ideas that appear repeatedly in the 'constructions' sections.

3. Notation for types of point and hyperplane for orthogonal groups

We attach the terms 'plus' and 'minus' to various notions connected with orthogonal groups. This usage is explained in Chapter 2, Section 5.

4. Projective dimensions and projective counting

Since the group stabilizing a vector also stabilizes its multiples, it is often sensible to use projective terminology, in which the $(k+1)$-dimensional subspaces of an $(n+1)$-dimensional vector

space are called the k-dimensional subspaces of an n-dimensional *projective space*. To avoid confusion, we usually use the terms *point, line, plane,* ... to indicate a space of *projective* dimension $0, 1, 2, \ldots$.

In projective counting, a vector is identified with its non-zero scalar multiples. Thus the 8 vectors from the centre of a cube to its vertices arise in 4 pairs $\{v, -v\}$, and so projectively speaking they yield just 4 distinct points. In such a situation we might write '... 2×4 vectors...' or '..., projectively, 4 vectors...' or, when we wish to indicate just which scalars are to be neglected '... 4 ($\pm$)-vectors...'. Formally, a ($\pm$)-vector is a pair $\{v, -v\}$, and an ω-vector (where $\omega^3 = 1$) is a triple $\{v, \omega v, \omega^2 v\}$.

5. Coordinates for vectors

We adopt various compact notations for vectors. For example $(2^8 0^{16})$ indicates a vector, or set of vectors, having some eight coordinates 2 and the remaining sixteen coordinates 0.

On occasion we indicate that we intend to apply all permutations of the appropriate Symmetric, Alternating, Cyclic, or Dihedral group by the corresponding superscript letter. Thus $(x, y, z, t)^A$ represents the twelve vectors obtained by all even permutations of the coordinates.

6. Quaternionic spaces

A fair number of our constructions involve quaternionic spaces, and as some readers will not be familiar with the necessary distinctions between the roles of the two kinds of multiplication, we state our conventions here. (Care is needed in comparisons with other sources.)

We use *left multiplication* for scalar products, and *right multiplication* for group actions. Thus if $x = (x_1, \ldots, x_n)$ is a vector, λ a scalar, and $\delta = diag(\delta_1, \ldots, \delta_n)$ a diagonal group element, then the scalar product of x by λ is

$$\lambda x = (\lambda x_1, \ldots, \lambda x_n),$$

while the image of x under δ is

$$x\delta = (x_1\delta_1, \ldots, x_n\delta_n).$$

The reader is cautioned that the map $x \to \lambda x$ is *not* a linear operation. Again, in a lattice L over some quaternionic ring R, we might say that $x \equiv y$ (modulo r) to mean that $x - y \in rL$. This does *not* usually imply that $\lambda x \equiv \lambda y$ (modulo r), but if δ is a group operation of some group acting on L, it *will* imply that $x\delta \equiv y\delta$ (modulo r).

7. Presentations

We write presentations in the format

$$\langle \text{generators} \mid \text{relations} \rangle$$

thus for example

$$\langle a, b \mid a^2 = b^3 = (ab)^5 = 1 \rangle$$

is a presentation for A_5. Relations placed in square brackets are redundant.

Coxeter-type presentations

We represent certain relations by diagrams, in which each node refers to a generator g, and indicates the relation $g^2 = 1$. For any two such generators g and h, we have the further relation

$gh = hg$, or $(gh)^2 = 1$, if the corresponding nodes are not joined,
$(gh)^3 = 1$, if they are joined by an unmarked edge,
$(gh)^n = 1$, if they are joined by an edge marked n.

This notation is often combined with the '$\langle \ldots \mid \ldots \rangle$' format, and additional relations may be explicitly adjoined. On occasions we specify certain relations, and then write '+ more relations(?)'—this means that the group certainly satisfies the specified relations, but we do not know whether they suffice for a presentation.

Many interesting presentations for particular groups can be deduced from the information on pages 232–3.

Notations for particular presentations (after Coxeter and Moser)

(l, m, n)	$R^l = S^m = T^n = RST = 1$, or $R^l = S^m = (RS)^n = 1$
$\langle l, m, n \rangle$	$R^l = S^m = T^n = RST$
$(l, m \mid n, k)$	$R^l = S^m = (RS)^n = (R^{-1}S)^k = 1$
$(l, m, n; q)$	$R^l = S^m = T^n = RST = (TSR)^q = 1$, or
	$R^l = S^m = (RS)^n = (R^{-1}S^{-1}RS)^q = 1$
$G^{p,q,r}$	$A^p = B^q = C^r = (AB)^2 = (BC)^2 = (CA)^2$
	$= (ABC)^2 = 1$, or
	$X^2 = Y^2 = (XY)^2 = 1$, and
	$1 = T^2 = (XT)^p = (YT)^q = (XYT)^r$
$G^{p,q,r,s,t,u,v}$	$X^2 = Y^2 = Z^2 = (XY)^2 = (YZ)^2 = (ZX)^2$
	$= 1$, and
	$1 = T^2 = (XT)^p = (YT)^q = (XYT)^r =$
	$(ZT)^s = (XZT)^t = (YZT)^u = (XYZT)^v$

5

How to read this ATLAS: information about subgroups and their structure

1. The maximal subgroups sections

A *maximal subgroup* H of G is a proper subgroup of G that is contained in no strictly larger proper subgroup of G. Whenever we have been able to do so, under the heading 'maximal subgroups' we have listed all the maximal subgroups of G up to conjugacy. On other occasions, we have modified this heading appropriately, or made some explicit qualification.

For each of the listed subgroups H of G, we usually give, in successive columns:

- its *order*
- its *index* in G
- its *structure* in the notation described at the end of this section
- for each automorphic extension $G.A$ of G, the *fusion behaviour* of H under A, and the associated maximal subgroups of $G.A$
- the *permutation character* of G on the cosets of H, when this is sufficiently simple,
- and finally various ways to *specify* a subgroup of type H in G.

In the column for an automorphic extension $G.A$,

- a *splitting symbol* (:) indicates that some conjugate of H is invariant under automorphisms of G that suffice to generate $G.A$ modulo G. (It then gives rise to an 'ordinary' maximal subgroup $H.A$ of $G.A$.)
- a *fusion join* (|) is used to show that several isomorphic groups H_i that are not conjugate in G become conjugate in $G.A$.

These symbols may be followed by structure-symbols for the 'ordinary' and 'novel' maximal subgroups of $G.A$. The maximal subgroups K of $G.A$ are of three types:

- *Trivialities*: these are the groups $G.B$, where B is a maximal subgroup of A. They are ignored in our tables.
- *Ordinaries*: if H is invariant under some automorphisms of G that generate $G.A$ modulo G, it extends to a maximal subgroup $K=H.A$ of $G.A$. In this case, we write the structure of K immediately after the corresponding splitting symbol. The letter H, when used, refers to the corresponding maximal subgroup of G.
- *Novelties*. It can happen that the intersection of K with G is a non-maximal proper subgroup of G. In such cases K is called a *novel* subgroup of $G.A$, and we have written its structure in the row corresponding to one of the maximal subgroups H of G that contains $K \cap G$.

Any maximal subgroup of $G.A$ that occurs after a fusion marker is a novelty; but novelties can also occur after a splitting symbol, in which case they are written *after* the corresponding 'ordinary' maximal subgroup $H.A$.

The *permutation character* of G associated with H is the character of the permutation representation of G acting by right multiplication on the right cosets of H in G. The irreducible constituents of this representation are indicated by their degrees followed by lower case letters a, b, c, . . . , which indicate the successive irreducible representations of G of that degree, in the order in which they appear in the ATLAS character table. A sequence of small letters (not necessarily distinct) after a single number indicates a sum of irreducible constituents all of the same degree. Thus

$$1a+45ab+216a+342aac$$

would be used to abbreviate

$$1a+45a+45b+216a+342a+342a+342c.$$

The *specifications* of subgroups H give information which might help to locate a copy of H inside G. An *abstract specification* expresses H as the normalizer in G of some element or subgroup, or alternatively as the centralizer in G of an outer automorphism. We indicate these (respectively) by writing $N(\ldots)$ or $C(\ldots)$, where the parentheses contain information about the conjugacy classes of the groups being normalized or centralized. The form $C(\ldots)$ is *only* used for the centralizers of *outer* automorphisms.

The class of a cyclic subgroup is indicated by its order, followed by the tag letters of its generators (see 'Class names', Chapter 7, Section 5): subscripts are used to count cyclic subgroups in a larger group, and superscripts indicate direct powers of groups. Thus the symbols below would be used for the normalizers in G of elements or groups of the indicated forms:

$N(2A)$:	an involution in G, of class $2A$.
$C(2B)$:	an outer automorphism of G, of class $2B$.
$C(2)$:	an outer automorphism of order 2 and unspecified class
$N(3A)$:	a group of order 3, with each generator in class $3A$.
$N(5AB)$:	a group of order 5, containing both classes $5A$ and $5B$.
$N(2A^2)$:	a fourgroup, whose involutions are in class $2A$.
$N(3^3)=N(3AB_4C_3D_6)$:	an elementary abelian group of order 27, whose 13 cyclic subgroups number 4 containing both classes $3A$ and $3B$, 3 containing $3C$ only, 6 containing $3D$ only (neglecting the identity element).
$N(2^6)$:	an elementary abelian group of order 2^6, unspecified classes.
$N(2A, 3B, 5CD)$:	an A_5, containing elements of classes $2A$, $3B$, $5C$, $5D$.
$N(2A, 3B, 5CD)^2$:	the direct product of two such A_5 groups.
$N(2A, 2C, 3A, 3B, \ldots)$:	a group containing elements of the indicated classes, among others.

The type of the group being normalized, when it is not obvious, can usually be deduced from the structure information about H. In the case of a non-abelian simple group S that is treated elsewhere in this ATLAS, the conjugacy classes in G of the non-trivial cyclic subgroups of S are listed in the order in which the classes appear in the ATLAS character table for S.

The remaining *specifications* describe subgroups, where possible, as the stabilizers of objects that arise naturally in the various *constructions* for G and related groups. The appropriate column is headed by a keyword which hints at the construction(s) referred to. The entry against a group H hints at an object whose stabilizer is a copy of H. These stabilizers should always be understood in the widest possible sense, so that for instance the stabilizer of a 'vector' would be the set of all group elements that fix that vector up to scalar multiplication (its *projective*

stabilizer). For this reason, we have a slight bias towards projective terminology in these columns.

There are many generic involvements of small Chevalley groups S in greater ones G. Thus $X_n(q^2)$ involves $X_n(q)$, $A_{mn-1}(q)$ involves $A_{n-1}(q)$ wr S_m, and $B_3(q)$ involves $G_2(q)$, which in turn involves both $A_2(q)$ and ${}^2A_2(q)$. We indicate these by writing just the name of S in the appropriate column of the maximal subgroup table for G, even though the actual maximal subgroup of G is often not just the group S, but a more complicated group involving S in its composition series. The structure column should supply the extra information.

2. Notations for group structures

There are many different ways in which structures of groups are indicated in the literature. We recommend the convenient ones below, and have used many of them in our tables of maximal subgroups and elsewhere in this ATLAS.

The notations C_m (*cyclic*), D_m (*dihedral*), Q_m (*quaternionic*, or *dicyclic*), E_m (*elementary abelian*), and X_m or X_m^+ or X_m^- (*extraspecial*), are often used for groups of order m with the indicated structures. (The reader should note that some authors use D_m and Q_m for the dihedral and quaternionic groups of order $2m$ rather than m.) The cyclic, dihedral, and quaternionic groups are defined by the presentations

$$\begin{array}{llll} C_m: & a^m=1 & & \\ D_m: & a^{\frac{1}{2}m}=1, & b^2=1, & b^{-1}ab=a^{-1} \quad (m \text{ even}) \\ Q_m: & a^{\frac{1}{2}m}=1, & b^2=a^{\frac{1}{4}m}, & b^{-1}ab=a^{-1} \quad (4 \text{ divides } m), \end{array}$$

and the elementary abelian and extraspecial groups are described later. The particular group Q_8 is the *quaternion group*, presented by $ij=k$, $jk=i$, $ki=j$, or by $i^2=j^2=k^2=ijk$, in which the common value is -1, a central element of order 2.

There are various ways to combine groups:

$A \times B$ is the *direct product*, or *Cartesian product*, of A and B. It may be defined as the set of ordered pairs (a, b) $(a \in A, b \in B)$, with $(a, b)(a', b') = (aa', bb')$.

$A.B$ or AB denotes any group having a normal subgroup of structure A, for which the corresponding quotient group has structure B. This is called an *upward extension* of A by B, or a *downward extension* of B by A.

$A:B$ or $A:^{\phi}B$ indicates a case of $A.B$ which is a *split extension*, or *semi-direct product*. The structure can be completely described by giving the homomorphism $\phi: B \to Aut(A)$ which shows how B acts by conjugation on A. It may be defined to consist of the ordered pairs (b, a) $(b \in B, a \in A)$, with $(b, a)(b', a') = (bb', a^{\phi(b')}a')$.

$A \cdot B$ indicates any case of $A.B$ which is *not* a split extension.

$A \circ B$ or $A \circ_C B$ indicates the *central product* of A and B over their common central subgroup C. Formally, we have injections $\alpha: C \to A$ and $\beta: C \to B$ of the abstract group C into the centres of A and B, and $A \circ B$ is the quotient of $A \times B$ by the set of ordered pairs of the form $(\alpha(c), \beta(c))$ $(c \in C)$. When it is omitted from the notation, C is usually understood to take the largest possible value.

$A \triangle B$ or $A \triangle_D B$ indicates a *diagonal product* of A and B over their common homomorphic image D. Formally, we have homomorphisms $\gamma: A \to D$ and $\delta: B \to D$ from A and B onto D, and $A \triangle B$ is the subgroup of $A \times B$ consisting of the (a, b) for which $\gamma(a) = \delta(b)$. When D is omitted from the notation, it is usually understood to take the largest possible value.

Central and diagonal products may have more than two factors. The notation $\frac{1}{2}(A \times B)$ denotes a diagonal product in which D has order 2.

$A \triangle\!\!\!\circ B$ or $A \circ_C \triangle_D B$ can be used for a *central-diagonal* product. For suitable groups, and with notations as above, this consists of the ordered pairs (a, b) for which $\gamma(a) = \delta(b)$ in D, taken modulo the pairs of form $(\alpha(c), \beta(c))$ $(c \in C)$.

$A \wr B$, or A wr B, the *wreath product* of A and B, is defined when B is a permutation group on n letters. It is the split extension $A^n:B$, where A^n is the direct product of n copies of A, on which B acts by permuting the factors.

In our structure symbols for complicated groups, we use the abbreviations:

$[m]$ for m an integer, denoting an arbitrary group of order m

m denoting a cyclic group of order m

A^n for the direct product of n groups of structure A. In particular

p^n where p is prime, indicates the elementary abelian group of that order.

Thus the two types of group of order four become

4 (the cyclic group), and 2^2 (the fourgroup).

p^{m+n} indicates a case of $p^m . p^n$, and so on.

Thus 2^{3+2+6} would indicate a 2-group having an elementary abelian normal subgroup of order 8 whose quotient contains a normal fourgroup modulo which becomes elementary abelian of order 2^6.

p^{1+2n} or p_+^{1+2n} or p_-^{1+2n} is used for the particular case of an extraspecial group. For each prime number p and positive n, there are just two types of extraspecial group, which are central products of n non-abelian groups of order p^3. For odd p, the subscript is + or − according as the group has exponent p or p^2. For $p=2$, it is + or − according as the central product has an even or odd number of quaternionic factors.

Products of three or more groups are left-associated, and should only be used when the indicated decomposition is invariant. Thus $A \cdot B:C$ means $(A \cdot B):C$, and implies the existence of a normal subgroup A.

Note to Chapters 6 and 7

The more complicated parts of these chapters are intended to be read in conjunction with one another. In these chapters, G usually denotes a simple group, with Schur multiplier M and outer automorphism group A. If ω is a root of unity, we shall sometimes say that a representation *represents a certain group element by* ω when we mean that it represents that element by ω times an identity matrix. The same phrase is applied to the character of that representation. Two characters of $M.G$ are said to belong to the same *cohort* if they represent the elements of M by the same roots of unity.

The unqualified word 'class' usually refers to a conjugacy class in a group G or $G.a$, while 'character' usually refers to a character of a group G or $m.G$.

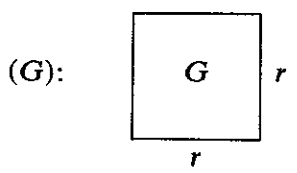
6

How to read this ATLAS: The map of an ATLAS character table

With each character table printed in this ATLAS we give a small map that explains to which groups the various portions of the table refer. The shape of this map depends on the Schur multiplier M and outer automorphism group A. We describe some of the simplest and most common cases first.

1. The case G (that is, trivial M and A)

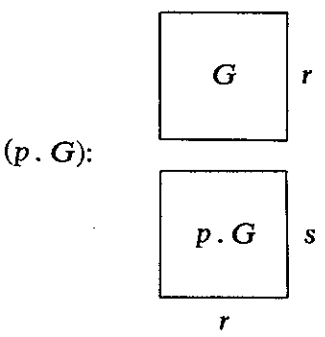
The map is a square



where the right-hand number r is the number of characters of G, and the lower one the number of classes. Of course these two numbers are equal, and usually called the *class number* of G.

2. The case $p.G$ (that is, M cyclic of prime order, A trivial)

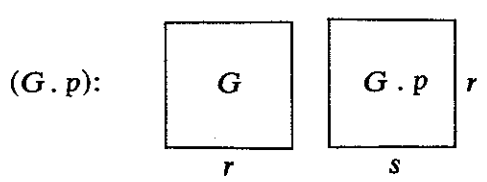
The map is a 'tower' of two squares



The upper square gives the same information as before. The lower one refers to one cohort of characters faithful on the central element, and tells us that there are s characters in that cohort. Since there are $p-1$ such cohorts, the class number of $p.G$ is $r+(p-1)s$. The orders of the elements in these classes are visible in the lifting order rows for $p.G$.

3. The case $G.p$ (M trivial, A cyclic of prime order)

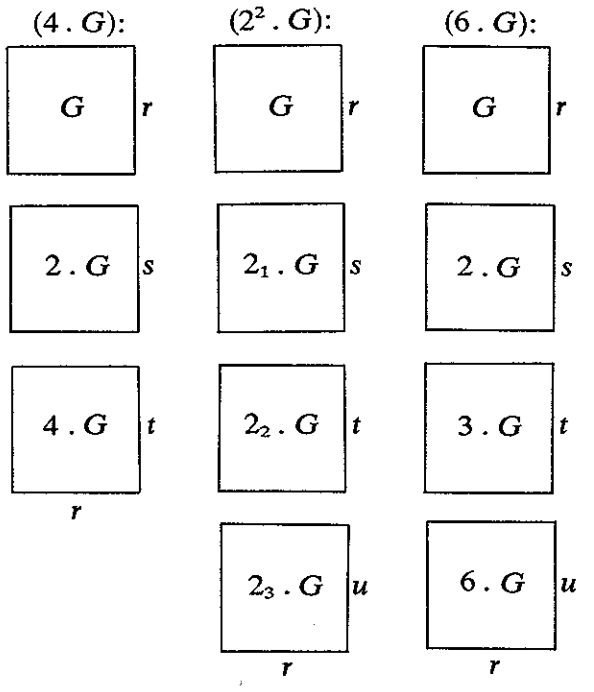
The map consists of two squares side by side:



This tells us that G has class number r, and that each other coset of G in $G.p$ contains s classes of $G.p$. Since $r-s$ characters of G fuse in sets of p, the class number of $G.p$ is $ps+(r-s)/p$, but is easiest found from the indicator column for $G.p$, which reveals the number of characters for that group.

4. The case $M.G$ (arbitrary multiplier, trivial automorphism group)

We illustrate the cases $4.G$, $2^2.G$, and $6.G$:



In the first case $(4.G)$, there is a cohort of r representations in which the central element is mapped to $+1$, and which we regard as representations of G, another cohort of s representations mapping that element to -1, which we regard as representations of $2.G$, and two cohorts of t representations each, mapping the central element to i or $-i$, which are faithful representations of $4.G$. The class numbers of G, $2.G$, and $4.G$ are r, $r+s$, and $r+s+2t$.

In the second case $(2^2.G)$, *no* irreducible representation can be faithful, since the central fourgroup must be represented by a group of roots of unity, which is necessarily cyclic. The map is a tower of four squares, the topmost one corresponding to the representations that are trivial on the central fourgroup, and so can be regarded as representations of G, and the other three corresponding to the three cyclic quotient groups, labelled 2_1, 2_2, 2_3, of the central fourgroup. The class numbers of G, $2_1.G$, $2_2.G$, $2_3.G$, and $2^2.G$ are r, $r+s$, $r+t$, $r+u$, and $r+s+t+u$.

In the third case $(6.G)$, the central subgroup has four cyclic quotients, of orders 1, 2, 3, and 6, and so we again have a tower of four squares, corresponding to groups G, $2.G$, $3.G$, and $6.G$. The map tells us that a central element of order 6 is represented by

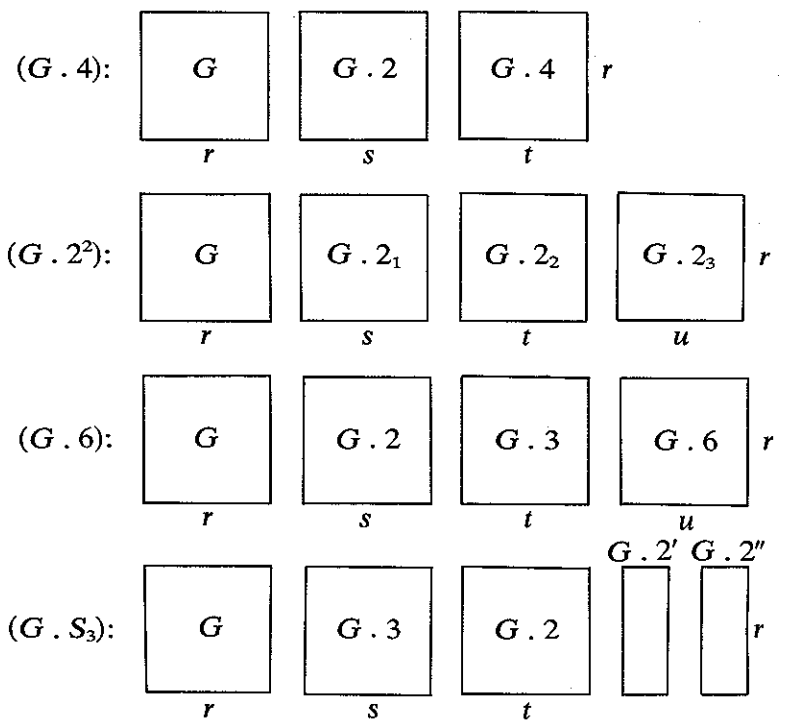
$$\begin{aligned} 1 &\text{ for } r \text{ characters} \\ -1 &\text{ for } s \text{ characters} \\ \omega \text{ or } \omega^2 &\text{ for } t \text{ characters each,} \\ -\omega \text{ or } -\omega^2 &\text{ for } u \text{ characters each,} \\ &\text{where } \omega = \exp(2\pi i/3). \end{aligned}$$

The class numbers of G, $2.G$, $3.G$, and $6.G$ are r, $r+s$, $r+2t$, $r+s+2t+2u$. The cohorts of characters representing the given central element by ω^2 and $-\omega^2$ are not printed.

In the general case $M.G$, there is a tower of squares, one for each cyclic quotient group (of order m, say) of the multiplier. The number to the right of a square is the number of characters in any of the cohorts which realize exactly that quotient group—there are $\phi(m)$ such cohorts, only one of which is printed.

5. The case $G.A$ (trivial multiplier, arbitrary outer automorphism group)

We illustrate the cases $G.4$, $G.2^2$, $G.6$, and $G.S_3$:

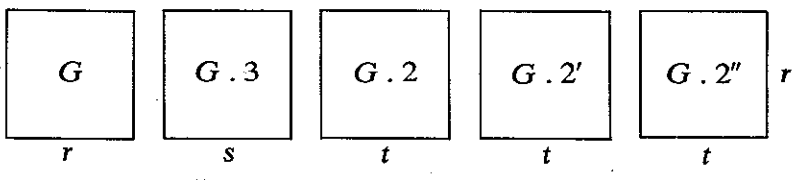


The 'dual' to the statement that any irreducible representation of $M.G$ realizes only a cyclic quotient of M is the much more obvious statement that any conjugacy class of $G.A$ is represented in some $G.a$, where a is a cyclic subgroup of A. Usually therefore an ATLAS table contains a detachment of columns for each cyclic subgroup of the outer automorphism group A. Each 'square' of the map corresponds to a *bicyclic* extension $m.G.a$ (m and a cyclic groups). The experienced user can often deduce information about non-bicyclic extensions, but we emphasize that 'officially'

ATLAS *tables give information only about bicyclic extensions.*

The first three of the above cases are the 'transposes' of the 'dual' cases $4.G$, $2^2.G$, and $6.G$, and we shall say little more about them. In the first case we have r classes of G, s classes of $G.2$ outside G, and $2t$ classes of $G.4$ outside $G.2$, but the exact class numbers of $G.2$ and $G.4$ are best obtained from the indicator columns for those groups. In the second case, we have r classes of G, and s, t, or u classes in the three extensions $G.2$ outside G. The class numbers of these can be found from the appropriate indicator columns, but in general there is no way to read the class number of $G.2^2$ from our table (it is not a bicyclic extension). The trouble is that a character of G that splits in (that is, extends to) each of the three extensions $G.2_1$, $G.2_2$, $G.2_3$ may either *split* to give four characters of $G.2^2$ or *fuse* to give just one, and there is no universal way to discover this from the character values.† This sort of problem does not arise in the third case, since the extending group is cyclic: a character which splits for $G.2$ and $G.3$ necessarily splits to give six characters for $G.6$.

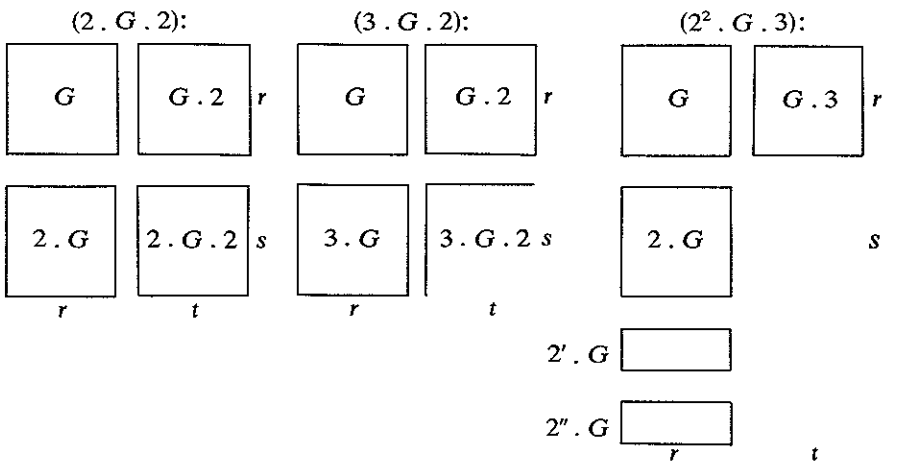
The fourth case, $G.S_3$ introduces new phenomena since the extending group is non-abelian. There are five cyclic subgroups of S_3, one of each order 1 and 3, and three of order 2, and so the full ATLAS table would have five detachments of columns, and a map:



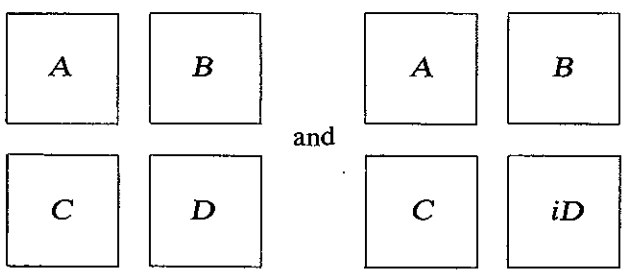
However, the last three blocks are images of each other under the automorphism group, and so contain much the same information. We therefore only print one of them in full (the *leader*), and just the indicator and fusion columns for the other two (its *followers*). In our maps, the 'squares' corresponding to follower cosets that have been suppressed in this way are 'squashed' in the way shown when we introduced this example.

6. The general case $M.G.A$

We illustrate three particular cases:



The first is the very common case $2.G.2$. The conventions about it are essentially the union of those for cases of form $2.G$ and $G.2$, and need little further explanation. However, it can be important to realize that any group $2.G.2$ has an isoclinic variant, and of course the group $2.G.2$ you are investigating may not be the one that we print. For the definitions, see 'Isoclinism' (Section 7) at the end of this chapter. The ATLAS tables for a group $2.G.2$ and its isoclinic variant $(2.G.2)^-$ have the forms

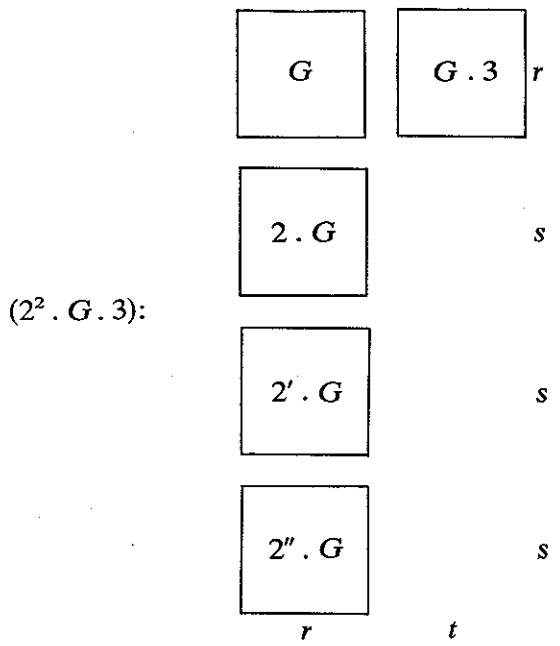


The orders of elements in the variant can be deduced from the statement that if g is an element of $2.G.2$ outside $2.G$, with $g^2 = h$, then in $(2.G.2)^-$ the corresponding element squares to $-h$, where -1 is the central element of order 2. If χ, χ^+, χ^- are corresponding characters of $2.G$, $2.G.2$, and $(2.G.2)^-$ respectively, faithful on the central element of order 2, then $\mathrm{ind}(\chi) = \mathrm{ind}(\chi^+) + \mathrm{ind}(\chi^-)$.

Our second example is for a group $3.G.2$, in which a central element z of order 3 in $3.G$ is inverted by the outer automorphisms. In this case each character of $3.G$ in the printed cohort that represents z by $\omega = \exp(2\pi i/3)$ fuses in $3.G.2$ with one from the unprinted cohort representing z by ω^2. It follows that all entries in the bottom right-hand portion of the table are zero. We therefore leave this portion blank, except for its fusion and indicator columns and lifting order rows, and represent this situation in our map by drawing only the leading two sides of the corresponding square. In such cases, the fusion column for $3.G.2$ will contain symbols $*$, which indicate fusion of the unprinted characters with either their own proxies or the proxies of other unprinted characters, as indicated by the joins (see Chapter 7, Section 18).

† When a character *does* extend to a group $G.A$ (A non-cyclic) the character values we print for the various cyclic extensions should all be part of a single character for $G.A$. In the case $G.2^2$ there is a simple rule which usually settles the question: if a *real-valued* (indicator + or −) character for G extends to characters α, β, γ for each of $G.2_1$, $G.2_2$, $G.2_3$ then it extends to $G.2^2$ if and only if an odd number of α, β, γ are real-valued characters.

The third example is for a group $2^2 . G . 3$, in which the multiplier has three cyclic quotients of order 2, permuted by the automorphism group. The full ATLAS table would contain a detachment of rows for each of the three corresponding groups $2 . G$, $2' . G$, $2'' . G$, and would have map:



We do not draw blocks $2 . G . 3$, $2' . G . 3$, $2'' . G . 3$ since the corresponding groups do not exist. However, the lower three blocks in this full table are images of each other under the automorphism group, and so contain much the same information. We therefore print only one of them in full (the *leader* cohort), and just the lifting order rows for the other two cohorts (its *followers*). (The lifting order rows for triple or higher order multiple covers that have been suppressed in this way are printed in a compressed format—see Chapter 7, Section 9.) In our maps, the 'squares' corresponding to the follower cosets that have been suppressed in this way are 'squashed' in the way shown when we introduced this example.

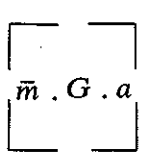
In a completely general case, the Full ATLAS Table (FAT) would contain a detachment of columns for each cyclic subgroup a of the outer automorphism group, and a detachment of rows for each cyclic quotient group m of the multiplier. If a transforms m into a different quotient group, there is no square on the map corresponding to $m . G . a$. If a acts non-trivially upon m, we print only two sides of the corresponding square, as in the case $3 . G . 2$, since the corresponding portion of the character table has all character values zero. There can only be non-zero character values when a centralizes m, and we then draw a full square in our map for the portion $m . G . a$.

In complicated cases, the table we print is usually smaller. The outer automorphism group will have various orbits on the cyclic subgroups of A or quotient groups of M, and from each orbit of the corresponding detachments of columns or rows we print just one in full, but retain only the indicator and fusion columns, or lifting order rows, for its followers. The portions of our maps corresponding to the suppressed objects are 'squashed'.

Of course in a complicated table we might have an orbit of $r > 1$ cosets, and also an orbit of $s > 1$ cohorts! In the cases we print, it happens that of the corresponding rs portions of the full ATLAS table all the ones that contain non-zero character values are equivalent under the automorphisms, and so we need only print one such portion in full.

For an example of a case when these rs portions include several non-zero orbits under the automorphisms, see the parts labelled x and y in our map for $O_8^+(3)$.

There are occasions when cyclic upward and downward extensions $G . a$ and $m . G$ exist, and a centralizes m, but there is no corresponding bicyclic extension $m . G . a$. They are indicated in our maps by a 'broken box'



which contains the name of a rather larger extension that does exist. We defer further explanations until we have explained the notion of isoclinism.

7. Isoclinism

The *commutator* $[x, y] = x^{-1}y^{-1}xy$ of two elements x, y of a group G is unaffected when we multiply x or y by an element of the centre $Z(G)$ of G, and of course its values lie in the *derived group* or *commutator subgroup* $G' = [G, G]$ of G (since this is defined as the group generated by all such commutators). We can therefore regard the commutator function as a map from $G/Z(G) \times G/Z(G)$ to G'. Two groups G and H are said to be *isoclinic* if they have 'the same' commutator map in this sense; in other words if there are isomorphisms $G/Z(G) \to H/Z(H)$ and $G' \to H'$ which identify the two commutator maps.

An equivalent and more concrete definition is to say that G and H are isoclinic if we can enlarge their centres so as to get isomorphic groups. This means that each of G and H can be embedded in a larger group K in such a way that K is generated by $Z(K)$ and G, and also by $Z(K)$ and H.

Philip Hall introduced isoclinism in connection with the enumeration of p-groups. It is also of vital importance in the theory of projective representations and the Schur multiplier. Indeed, any irreducible representation of G can be converted to one of H of the same degree, for which the representing matrices are scalar multiples of those that represent G. To see this, restrict the representation to $Z(G)$, when we obtain a set of scalar matrices to which we can adjoin others which extend this representation to one of $Z(K)$, and hence extend the original representation of G to one of K. The desired representation of H is now obtained by restriction.

Thus the dihedral and quaternionic groups of order 8 are isoclinic: the matrices $\pm\begin{pmatrix}1 & 0\\0 & 1\end{pmatrix}$, $\pm\begin{pmatrix}i & 0\\0 & -i\end{pmatrix}$, $\pm\begin{pmatrix}0 & 1\\1 & 0\end{pmatrix}$, $\pm\begin{pmatrix}0 & -i\\i & 0\end{pmatrix}$ represent the former, and by multiplying the last two pairs of matrices by the scalar matrix $\begin{pmatrix}i & 0\\0 & i\end{pmatrix}$ we obtain a representation of the latter. A similar phenomenon occurs with any faithful representation of a group $H = 2 . G . 2$. The representing matrices will be various matrices $\pm A$ (for elements of $2 . G$), and $\pm B$ (for the remaining elements of H), and there is an isoclinic group K, (also of structure $2 . G . 2$) represented by the matrices $\pm A$ and $\pm iB$. A group of structure $3 . G . 3$ is one of three isoclinic variants, in which the elements in the three cosets of the subgroup $3 . G$ are represented by matrices

$$\omega^n A,\ \omega^n B,\ \omega^n C$$
$$\omega^n A,\ \varepsilon\omega^n B,\ \varepsilon^2\omega^n C$$
$$\omega^n A,\ \varepsilon^2\omega^n B,\ \varepsilon\omega^n C,$$

where $\omega = \exp(2\pi i/3)$, $\varepsilon = \exp(2\pi i/9)$.

A *perfect* group (one for which $G = G'$) has a unique central extension $M . G$ realizing any quotient M of its Schur multiplier. Thus for example there is a unique proper cover $2 . A_n$ of the alternating group A_n for $n \geqslant 5$. For more general groups G, the appropriate groups $M . G$ are only unique up to isoclinism. Thus for example, the symmetric groups S_n $(n \geqslant 5)$ have two double covers, 2^+S_n and 2^-S_n, which can be converted into each other by multiplying the elements that lie above odd permutations by a new central element i, whose square is the central element of order 2 in either group. The one we tabulate is 2^+S_n, in which the transpositions of S_n lift to involutions.

There is a sense in which the different portions of an ATLAS character table (or the squares of its map) correspond to isoclinism classes of bicyclic extensions, rather than to the individual extensions whose characters we choose to print. Changing to a different group in the isoclinism class merely multiplies the associated portions of a table by various roots of unity (and affects their headings).

It can happen that upward and downward cyclic extensions

$G.a$ and $m.G$ exist, and the automorphisms of a centralize m, but no corresponding bicyclic extension $m.G.a$ exists. The relevant isoclinism class of extensions is well-defined, but happens to contain no group of the 'expected' order $|m|.|G|.|a|$. We illustrate with the case $G = A_6$, which has three cyclic automorphic extensions $G.2_1 = S_6$, $G.2_2 = PGL_2(9)$, and $G.2_3 =$ the 'Mathieu' group M_{10}.

The Schur double cover $2.G$, is categorically associated with G, and so any automorphism of G can be lifted to an automorphism of $2.G$. Now it happens that $G.2_1$ and $G.2_2$ are split extensions, from which it follows that there *do* exist groups $2.G.2_1$ and $2.G.2_2$ of the required type. To see this, take an involution x extending G to the appropriate $G.2_i$. Then the automorphism $g \to x^{-1}gx$ of G lifts to an automorphism θ_x, say, of $2.G$, and the split extension $(2.G):2$ of $2.G$ by this automorphism is the desired group $2.G.2_i$ $(i = 1, 2)$.

However, the group $G.2_3$ is a non-split extension of G. We can generate it by G together with an element x of order 4 with $x^2 = y$ in G. It turns out that the automorphism θ_x of $2.G$ obtained by lifting the automorphism $g \to x^{-1}gx$ *interchanges the two preimages of* y *in* $2.G$. It is therefore impossible to achieve this by an element of order 4 (in a putative group $2.G.2_3$) which squares to either preimage of y.

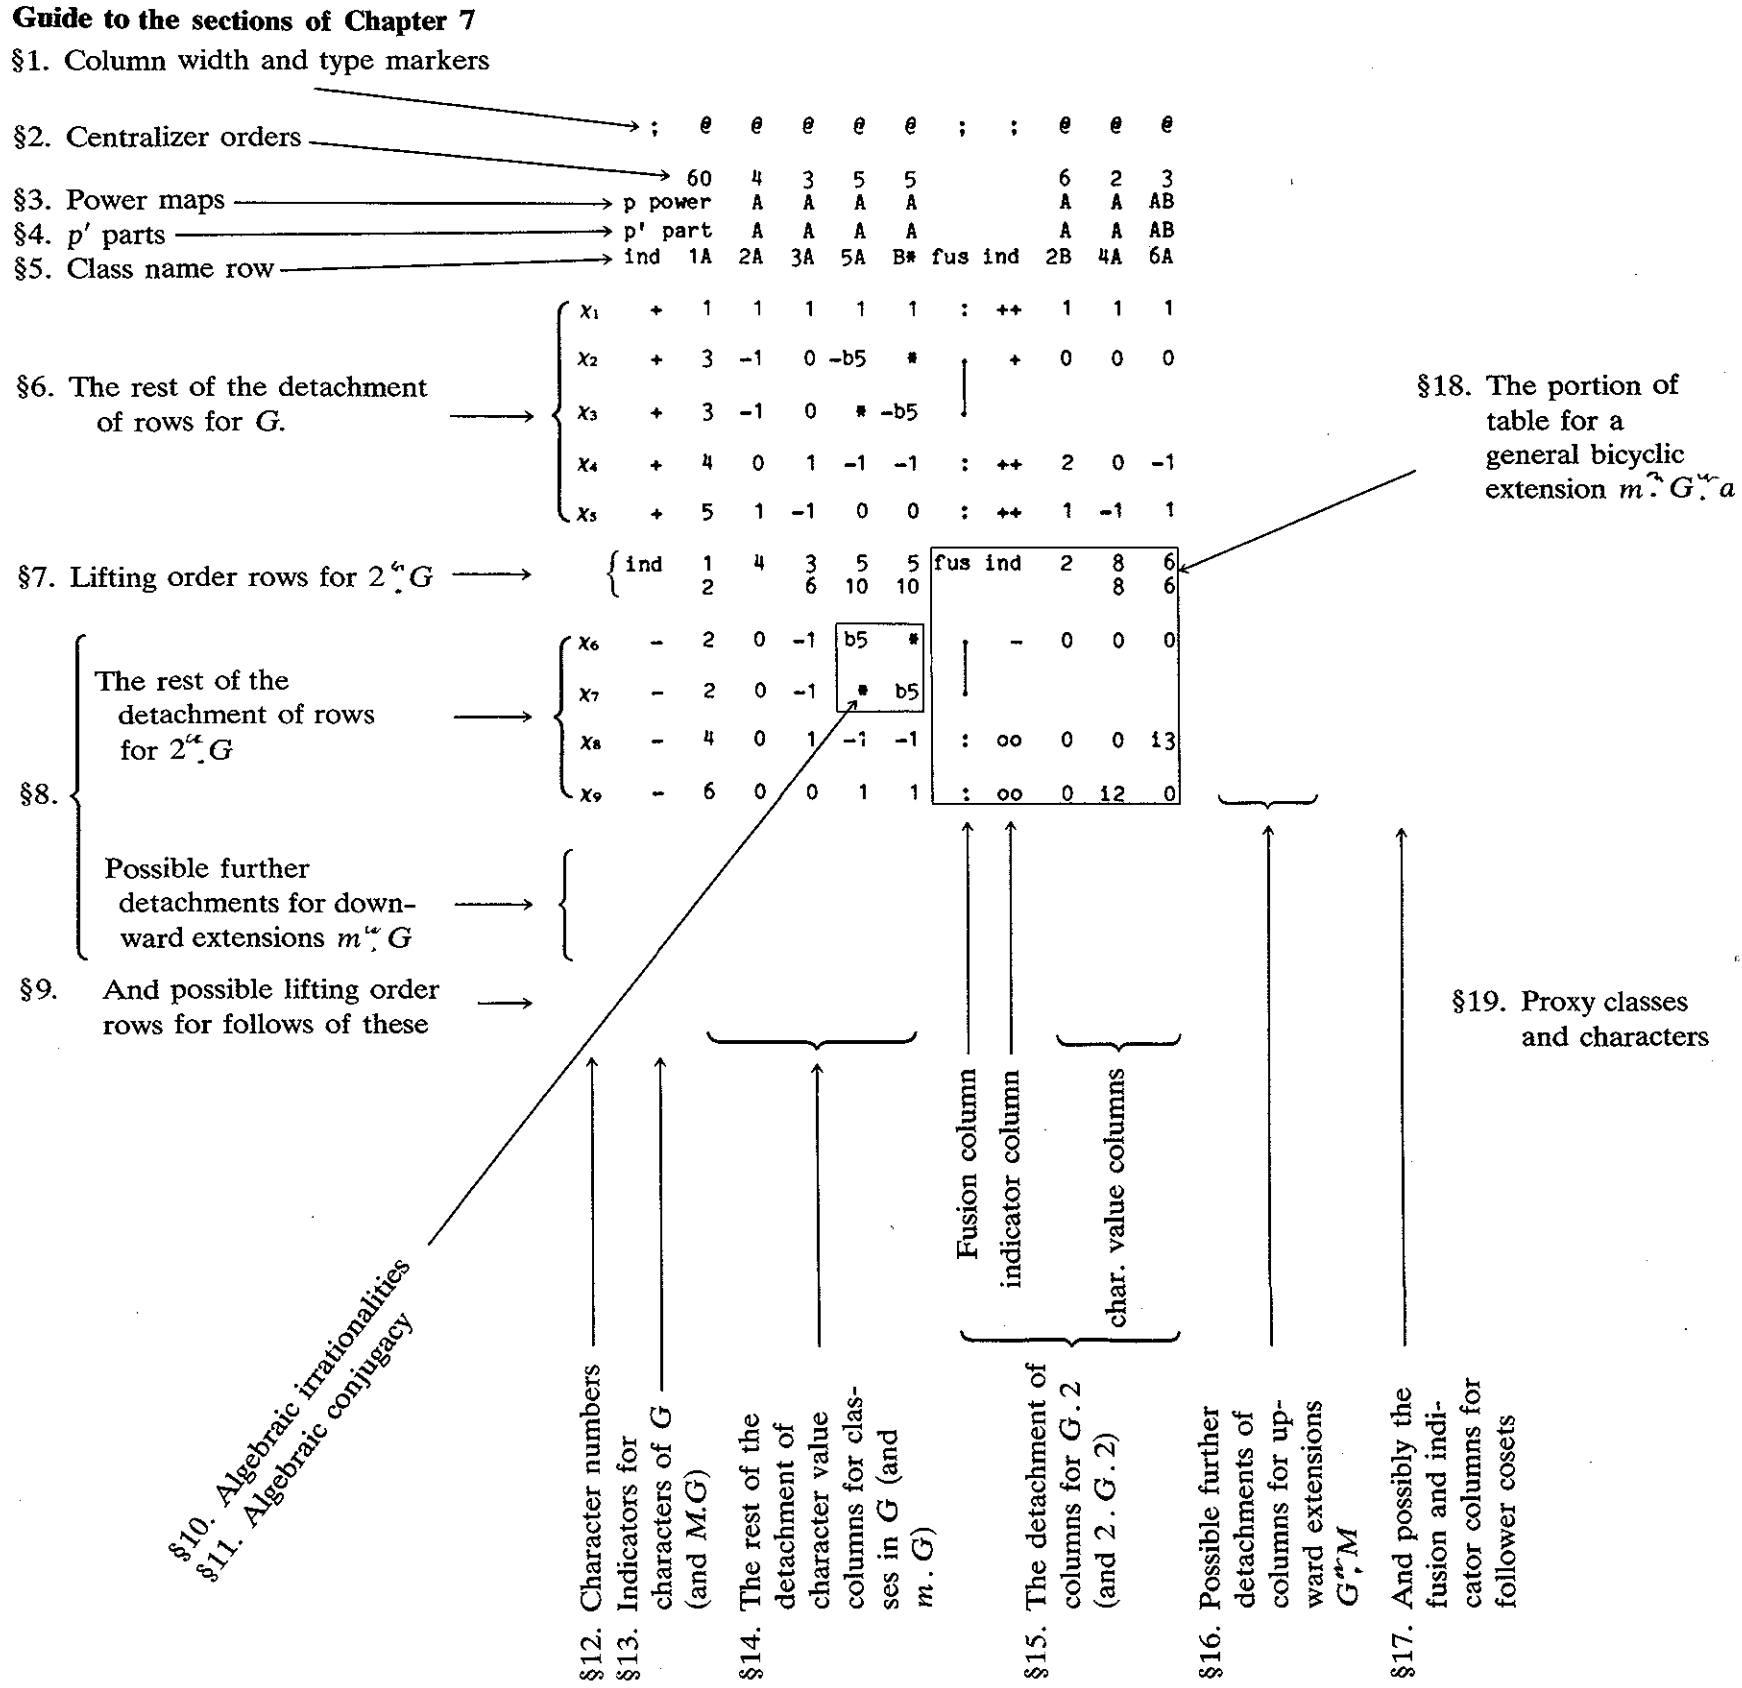
When such a case arises in this ATLAS, we draw a *broken box*, for example:

$$\boxed{4.G.2}$$

in the appropriate place on the map, containing the name of a larger extension that does exist. In our example, this is a group $4.G.2$ which can be obtained as the split extension of $2.G$ by the automorphism θ_x of order 4 just described. (There is also an extension of structure $2^2.G.2$ in this isoclinism class, but we prefer the bicyclic one.)

It is slightly easier in this example to see that no enveloping group of structure $2.G.2^2$ can exist. This is because the outer automorphism of S_6 interchanges the two isoclinism classes of groups $2S_6$. (It interchanges elements of cycle-types $2^1 1^4$ and 2^3, and just one of these lifts to an involution in either $2S_6$, and so neither of these groups can possess an automorphism of the required type.) We remark that the calculations needed to verify our assertions about this example can be performed in $\Gamma L_2(9)$.

Guide to the sections of Chapter 7



7

How to read this ATLAS: character tables

The Guide describes the parts of a typical ATLAS character table. We shall first describe it row-by-row, and then column-by-column. Much of the complexity of this description arises from the need to consider groups with arbitrary Schur multiplier and outer automorphism group—the reader who is not interested in complicated cases should find that the first few sections suffice.

1. Column width and type markers

The first row contains the symbol @ at the head of a column that later contains character values of some conjugacy class, and the symbol ; for one that contains fusion or indicator information.

If the table is read mechanically, this row can be used to determine the widths of the columns, which may be necessary since occasionally the entries in adjacent columns abut. The information in any column is right-justified.

2. Centralizer orders

The second and third rows give the order of the centralizer in G of the typical element of each class. Since the numbers are sometimes too large to fit in the appropriate portion of a single row, two rows are provided, the top one containing the leading digits of large numbers.

The numbers given are the orders of centralizers in the base group G, even for columns that refer to classes in a larger group $G.a$.

3. Power maps

The kth powers of the elements of a given class form another class. The resulting *power maps* between the classes can be found by repeated use of the *prime power maps*, the particular cases when k is prime.

The fourth row gives the tag letters (see Section 5, 'Class names') of the classes that contain the powers $g^p, g^q, g^r, \ldots$ of g, where $p<q<r<\ldots$ are the distinct prime divisors of the order of g. Thus if g has order 60, an entry ABC means that

$$g^2 \text{ is in class } 30A,\ g^3 \text{ in class } 20B,\ g^5 \text{ in class } 12C.$$

If k is a number prime to the order of g, the class of g^k can be found by applying the algebraic conjugacy operator $*k$ to the class of g.

It can happen that the pth power of an element of an automorphic extension $G.a$ does not lie in any of our chosen generator cosets (see Section 16). In such cases the tag letter given is that of the proxy class. We do not give complete power map information for groups $m.G$ and $m.G.a$. A good deal can be deduced from the orders of elements in those groups, and the power maps for the corresponding groups G and $G.a$.

4. p′-parts

If π is any set of primes, we can uniquely write

$$g = g(\pi).g(\pi') = g(\pi').g(\pi),$$

where π contains all the prime divisors of the order of $g(\pi)$, but none of those of the order of $g(\pi')$. The elements $g(\pi)$ and $g(\pi')$, which are certain powers of g, are respectively called the *π-part* and *π'-part* of g. When π contains a single prime p, we write $g(p)$ and $g(p')$ for these, and call them the *p-part* and *p'-part* of g.

The π-parts for general sets π can be found by repeated use of the p'-parts. The fifth row of the table gives the tag letters for $g(p'), g(q'), g(r'), \ldots$, where $p<q<r<\ldots$ are the distinct prime divisors of the order of g. We do not give complete information on the p' parts for multiple covers $m.G$.

5. Class names

The conjugacy classes that contain elements of order n are named $nA, nB, nC, \ldots$. The alphabet used here is potentially infinite, and reads

A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R,
S, T, U, V, W, X, Y, Z, A1, B1, . . . , A2, B2, ...

The *class name row* contains the following information:

The headings 'ind' and 'fus' for indicator and fusion columns;
'Master' class name entries, of form nX, meaning just that the column refers to a conjugacy class nX;
'Slave' class name entries, of form $Y*k$ (or $Y**k$, $Y**$, $Y*$), which refer to a class nY, and also give the information that nY can be obtained from the most recent 'master' class nX by applying the algebraic conjugacy operator $*k$ (or $**k$, $**$, $*$).

A 'master' class and the immediately subsequent 'slave' classes complete an *algebraically conjugate family* of classes. The algebraic conjugacy operators are defined on classes as follows:

$(nX)^{*k}$ contans the kth powers of elements of nX;
$(nX)^{**k}$ contains the $(-k)$th powers of elements of nX;
$(nX)^{**}$ contains the inverses of elements of nX; and
$(nX)^{*}$ is the class other than nX containing elements of order n that are powers of elements of nX, when this class is unique.

It is to be understood that k is prime to n.

The values of characters on these classes are the images of their values on nX under the appropriate algebraic conjugacies.

6. Character values, for characters of G

The typical row of the character table consists mostly of character values, together with indicator and fusion information that is described later. Usually the character values are ordinary integers, but certain algebraic irrationalities can also arise. In such cases we *either* print the ATLAS name for the desired irrationality in full, *or* just an algebraic conjugacy operator by which it can be obtained from a nearby entry in the same row. To be precise, this nearby entry can be any entry for a class in the same algebraically conjugate family as the desired one that *is* printed in full.

The complete ATLAS system of names for algebraic irrationalities is given later (Section 10). The following should

suffice for simple cases:

$$rN=\sqrt{N} \qquad zN=\exp(2\pi i/N)$$

$$iN=i\sqrt{N} \qquad yN=2\cos(2\pi/N)$$

$$bN=\begin{cases}\frac{1}{2}(-1+\sqrt{N}) & (N\equiv 1, \bmod 4)\\ \frac{1}{2}(-1+i\sqrt{N}) & (N\equiv -1, \bmod 4)\end{cases} \qquad mN=2i\sin(2\pi/N),$$

where of course i denotes $\sqrt{-1}$.

Any of these algebraic numbers can be expressed as a linear combination of nth roots of unity for some n. If k is prime to n, the algebraic conjugacy operator $*k$ acts on such numbers by replacing these roots of unity by their kth powers. The operator $**k$ is an abbreviation for $*(-k)$, and $**$ is the complex conjugation operator, which is $*(-1)$. The operator $*$ is defined for a quadratic number field, and replaces $r+s\sqrt{N}$ by $r-s\sqrt{N}$ (r, s rational, $\sqrt{N}$ irrational).

7. Lifting order rows for a group $m\,.\,G$

If G has a (cyclic) multiple cover $m\,.\,G$, then g will be the image of m distinct elements $g_0, g_1, \ldots, g_{m-1}$ of $m\,.\,G$. There will be some divisor d of m such that g_i will be conjugate (in $m\,.\,G$) to g_j just when i and j are congruent modulo d, so that $g_0, g_1, \ldots, g_{d-1}$ will represent the distinct conjugacy classes lying above the class of g.

For any such extension $m\,.\,G$ for which characters are printed, we give m *lifting order rows* which contain the orders of the elements $g_0, g_1, \ldots, g_{d-1}$ (and by implication, the number d). There is a slightly different convention for cases when the characters are not printed (Section 9).

8. Character values for a group $m\,.\,G$

We first describe the case $m=2$. Let Ω be the central element of order 2. Any irreducible representation of $2\,.\,G$ must represent Ω by I or $-I$, where I is the appropriate identity matrix, and in the former case we regard the representation as being one of G. In the latter case, the corresponding row contains the indicator of χ, followed by its particular values $\chi(g_0)$, the remaining values being deducible since $\chi(g_1)=-\chi(g_0)$ for these characters.

Thus the character table of $2A_5$ is:

class	$1A_0$	$1A_1$	$2A_0$	$3A_0$	$3A_1$	$5A_0$	$5A_1$	$5B_0$	$5B_1$
order	1	2	4	3	6	5	10	5	10
+	1	1	1	1	1	1	1	1	1
+	3	3	−1	−0	0	$-b_5$	$-b_5$	$-b_5^*$	$-b_5^*$
+	3	3	−1	0	0	$-b_5^*$	$-b_5^*$	$-b_5$	$-b_5$
+	4	4	0	1	1	−1	−1	−1	−1
+	5	5	1	−1	−1	0	0	0	0
−	2	−2	0	−1	1	b_5	$-b_5$	b_5^*	$-b_5^*$
−	2	−2	0	−1	1	b_5^*	$-b_5^*$	b_5	$-b_5$
−	4	−4	0	1	−1	−1	1	−1	1
−	6	−6	0	0	0	1	−1	1	−1

In general, an irreducible character χ of a central extension $M\,.\,G$ of G restricts to M to give a scalar multiple of some linear (that is, degree 1) character χ' of M. The set of χ yielding a particular χ' on M will be called a *cohort* of characters. The values of χ' on M will be all the roots of unity whose order divides some m, and so the characters of the cohort can be regarded as characters of some *cyclic* extension $m\,.\,G$, a quotient of $M\,.\,G$.

For each such cyclic extension $m\,.\,G$, we choose a particular cohort of characters χ for which $\chi'(\Omega)=\omega I$, where Ω generates the central cyclic subgroup of $m\,.\,G$, and ω is a particular primitive mth root of unity. The chosen cohort will be called the *generator cohort* for $m\,.\,G$. A character χ of $m\,.\,G$ from a cohort with $\chi'(\Omega)=\omega_1 I$, where ω_1 is another primitive mth root of unity, is algebraically conjugate to a character from the generator cohort, which we shall call its *proxy*. (The precise rules relating characters to their proxies will be defined in Section 19.)

The detachment of rows for a generator cohort for which we print character values is headed by m lifting order rows as described in the previous section. Each subsequent row really represents $\phi(m)$ algebraically conjugate characters, the printed one being that from the generator cohort, which acts as proxy for the others.

Whenever a row of an ATLAS table is used to represent $M\geqslant 2$ algebraically conjugate characters, the entry in its indicator column is $+M$, $\circ M$, $-M$ according as the indicators (see Section 13) of these characters are +, ○, − (they are necessarily the same). So for $m\geqslant 3$, the characters we print for the generator cohort of a group $m\,.\,G$ all represent $\phi(m)=M$ characters, and are headed by the entry $\circ M$ in the indicator column (their values include multiples of the non-real mth roots of unity).

We illustrate all this by describing the generator cohort of characters for $3A_6$. The appropriate portion of the ATLAS table reads:

ind	1	2	3	3	4	5	5	
	3	6			12	15	15	
	3	6			12	15	15	
χ_{14}	o2	3	−1	0	0	1	−b5	*
χ_{15}	o2	3	−1	0	0	1	*	−b5
χ_{16}	o2	6	2	0	0	0	1	1
χ_{17}	o2	9	1	0	0	1	−1	−1
χ_{18}	o2	15	−1	0	0	−1	0	0

The entries in the lifting order rows give us the number of conjugacy classes (17) of $3A_6$ and the orders of the elements they contain. The characters of this cohort, if written out at length, would look like:

class of g	$1A_0$	$1A_1$	$1A_2$	$2A_0$	$2A_1$	$2A_2$	$3A_0$	$3B_0$
order of g	1	3	3	2	6	6	3	3
values of χ_{14}:	3	3ω	$3\bar{\omega}$	−1	$-\omega$	$-\bar{\omega}$	0	0
χ_{15}:	3	3ω	$3\bar{\omega}$	−1	$-\omega$	$-\bar{\omega}$	0	0
χ_{16}:	6	6ω	$6\bar{\omega}$	2	2ω	$2\bar{\omega}$	0	0
χ_{17}:	9	9ω	$9\bar{\omega}$	1	ω	$\bar{\omega}$	0	0
χ_{18}:	15	15ω	$15\bar{\omega}$	−1	$-\omega$	$-\bar{\omega}$	0	0

$4A_0$	$4A_1$	$4A_2$	$5A_0$	$5A_1$	$5A_2$	$5B_0$	$5B_1$	$5B_2$
4	12	12	5	15	15	5	15	15
1	ω	$\bar{\omega}$	$-b_5$	$-b_5\omega$	$-b_5\bar{\omega}$	$-b_5^*$	$-b_5^*\omega$	$-b_5^*\bar{\omega}$
1	ω	$\bar{\omega}$	$-b_5^*$	$-b_5^*\omega$	$-b_5^*\bar{\omega}$	$-b_5$	$-b_5\omega$	$-b_5\bar{\omega}$
0	0	0	1	ω	$\bar{\omega}$	1	ω	$\bar{\omega}$
1	ω	$\bar{\omega}$	−1	$-\omega$	$-\bar{\omega}$	−1	$-\omega$	$-\bar{\omega}$
−1	$-\omega$	$-\bar{\omega}$	0	0	0	0	0	0

where $\omega=\exp(2\pi i/3)$ is a primitive cube root of unity. The alternative cohort can be obtained by applying any algebraic conjugacy operation that takes ω to $\bar{\omega}$, and the complex conjugacy operator $**$ is the nicest choice. The trivial cohort consisting of the 7 characters for G itself, supplemented by these two cohorts of 5 characters each for $3\,.\,G$, gives the entire set of 17 characters for $3\,.\,G$.

9. Follower cohorts

A rather larger table than the one we print is what we call the Full Atlas Table (FAT), which would contain a full detachment of rows corresponding to the generator cohort of each downward cyclic extension $m\,.\,G$ of G. But for complicated tables the FAT table would be *too* fat, since there can be several cyclic covers $m\,.\,G$ that are equivalent under the action of $Aut(G)$. We thin it out by selecting only one (*leader*) extension $m\,.\,G$ for each family equivalent under $Aut(G)$. The detachment of rows for the leader extension is printed in full, and followed by only the lifting order rows for the remaining (*follower*) extensions equivalent to it.

To save space, the lifting order rows are printed in a slightly different format, needing only two rows. The top row, headed

'and' gives the order of the canonical inverse images g_0 of elements g in G. (We always choose g_0 to have the smallest order of any inverse image of g.) The bottom row, headed 'no'. gives the number of distinct conjugacy classes of $m.G$ represented by the inverse images of g (when this number exceeds 1).

10. The ATLAS notation for algebraic numbers

Note. For greater legibility in this Introduction, we use subscripts and superscripts as in ordinary mathematical practice. However, our notation for algebraic numbers has been designed so that it can all be written on one line without loss of information. Thus what we here write as $y_{24}^{\prime\prime *5}$ appears elsewhere in our tables and text as y''24*5.

As usual, we let i denote a fixed square root of -1. Then for suitable integers N we define:

$$z_N = \exp(2\pi i/N) = z, \text{ say}$$

$$b_N = \tfrac{1}{2}\sum_{t=1}^{N-1} z^{t^2} \quad (N \equiv 1 \bmod 2) \qquad y_N = z + z^n = 2\cos(2\pi/N) \qquad (n = n_2 = -1)$$

$$c_N = \tfrac{1}{3}\sum_{t=1}^{N-1} z^{t^3} \quad (N \equiv 1 \bmod 3) \qquad x_N = z + z^n + z^{n^2} \qquad (n = n_3)$$

$$d_N = \tfrac{1}{4}\sum_{t=1}^{N-1} z^{t^4} \quad (N \equiv 1 \bmod 4) \qquad w_N = z + z^n + z^{n^2} + z^{n^3} \qquad (n = n_4)$$

$$e_N = \tfrac{1}{5}\sum_{t=1}^{N-1} z^{t^5} \quad (N \equiv 1 \bmod 5) \qquad v_N = z + z^n + z^{n^2} + z^{n^3} + z^{n^4} \qquad (n = n_5)$$

$$f_N = \tfrac{1}{6}\sum_{t=1}^{N-1} z^{t^6} \quad (N \equiv 1 \bmod 6) \qquad u_N = z + z^n + z^{n^2} + \ldots + z^{n^5} \qquad (n = n_6)$$

$$g_N = \tfrac{1}{7}\sum_{t=1}^{N-1} z^{t^7} \quad (N \equiv 1 \bmod 7) \qquad t_N = z + z^n + z^{n^2} + \ldots + z^{n^6} \qquad (n = n_7)$$

$$h_N = \tfrac{1}{8}\sum_{t=1}^{N-1} z^{t^8} \quad (N \equiv 1 \bmod 8) \qquad s_N = z + z^n + z^{n^2} + \ldots + z^{n^7} \qquad (n = n_8)$$

$$i_N = i\sqrt{N} \qquad r_N = \sqrt{N}$$

$$m_N = z - z^n = 2(\sin 2\pi/N)i \qquad (n = n_2 = -1)$$

$$l_N = z - z^n + z^{n^2} - z^{n^3} \qquad (n = n_4)$$

$$k_N = z - z^n + \ldots - z^{n^5} \qquad (n = n_6)$$

$$j_N = z - z^n + \ldots - z^{n^7} \qquad (n = n_8).$$

It follows from a famous theorem of Gauss that

$$b_N = \begin{cases} \tfrac{1}{2}(-1+\sqrt{N}) & \text{if } N \equiv 1, \bmod 4 \\ \tfrac{1}{2}(-1+i\sqrt{N}) & \text{if } N \equiv -1, \bmod 4. \end{cases}$$

The numbers $n_2, n_3, \ldots, n_8$ are defined as follows: n_k is the smallest integer in absolute value that has multiplicative order exactly k modulo N, the positive value being chosen when n_k and $-n_k$ have the same order. (This definition ensures that $n_2 = -1$.)

Further algebraic numbers

$$y'_N, y''_N, y'''_N, \ldots, x'_N, x''_N, \ldots, j'_N, j''_N, \ldots,$$

are obtained on replacing n_k in the above definitions by $n'_k, n''_k, \ldots$, where

$$n_k, n_k', n_k'', n_k''', \ldots$$

are *all* the numbers of multiplicative order exactly k modulo N, chosen in the order of preference

$$1, -1, 2, -2, 3, -3, 4, -4, \ldots.$$

Thus the numbers of exact order 2 modulo 24 are, in this order,

$$-1, 5, -5, 7, -7, 11, \ldots,$$

and so we have

$$y'_{24} = z_{24} + z_{24}^{5}, \quad y''_{24} = z_{24} + z_{24}^{-5}, \quad y'''_{24} = z_{24} + z_{24}^{7}, \ldots.$$

The irrational numbers that appear in ATLAS character tables are named in terms of the *atomic* irrationalities we have just defined. However, when several neighbouring numbers in a row are algebraically conjugate, we often print only some of them in full, and for the others indicate only the algebraic conjugacy by which they can be obtained from their neighbours.

Thus the ATLAS table for A_5 contains the 2×2 block of entries

$$\begin{array}{ccc} & 5A & 5B \\ \chi_2 & -b5 & * \\ \chi_3 & * & -b5 \end{array}, \text{ which abbreviates } \begin{array}{ccc} & 5A & 5B \\ \chi_2 & -b_5 & -b_5^*, \\ \chi_3 & -b_5^* & -b_5 \end{array}$$

or, in full,

$$\begin{array}{ccc} & 5A & 5B \\ \chi_2 & -\tfrac{1}{2}(-1+\sqrt{5}) & -\tfrac{1}{2}(-1-\sqrt{5}) \\ \chi_3 & -\tfrac{1}{2}(-1-\sqrt{5}) & -\tfrac{1}{2}(-1+\sqrt{5}), \end{array}$$

because in this instance $*$ indicates the algebraic conjugacy that changes the sign of $\sqrt{5}$, and we have $b_5 = \tfrac{1}{2}(-1+\sqrt{5})$ by Gauss's theorem.

In general, when only the name ($*k$, $**k$, $**$, or $*$) of an algebraic conjugacy appears as a character value entry, it is to be applied to an entry in the same row whose value is given in full, and which refers to a class in the same algebraically conjugate family as the desired one. Such families can be detected by examining the class name row (Section 5). The conjugacy $*k$ replaces nth roots of unity by their kth powers, whenever k is prime to n, and we have

$$**k = *(-k)$$
$$** = *(-1),$$

while $*$ is only applied to a quadratic number field, and takes $r + s\sqrt{N}$ to $r - s\sqrt{N}$ (r, s rational, $\sqrt{N}$ irrational).

The ampersand convention

On rare occasions, we have used another convention to abbreviate some very complicated irrationalities. If q_N denotes any of our atomic irrationalities (e.g. y_{24}''), then linear combinations of algebraic conjugates of q_N are abbreviated as in the following examples:

2qN+3&5-4&7+&9	means $2q_N + 3q_N^{*5} - 4q_N^{*7} + q_N^{*9}$
4qN&3&5&7-3&11	means $4(q_N + q_N^{*3} + q_N^{*5} + q_N^{*7}) - 3q_N^{*11}$
4qN*3&5+&7	means $4(q_N^{*3} + q_N^{*5}) + q_N^{*7}$.

(Only much simpler examples actually occur!) To explain the 'ampersand' syntax in general we remark that '&k' is interpreted as q_N^{*k}, where q_N is the most recently named atomic irrationality, and that the scope of any premultiplying coefficient is broken by a + or − sign, but not by & or $*k$. The algebraic conjugations indicated by the ampersands apply directly to the *atomic* irrationality q_N, even when, as in our last example, q_N first appears with another conjugacy $*k$.

11. A note on algebraic conjugacy

Our algebraic conjugacy operators $*k$ operate on a wide variety of concepts, always defined with respect to some number n prime to k:

Algebraic numbers in the field of nth roots of unity—this is the primitive notion: the action was defined in Section 10.

Elements g of order n: $*k$ takes g to g^k.

The corresponding conjugacy classes: $*k$ takes the class of g to that of g^k.

Cosets C of G in an upward extension of G, where $C^n = G$: $*k$ takes C to C^k.

Characters defined in the field of nth roots of unity: $*k$ acts on their values

Cohorts C of characters faithful exactly on a cyclic quotient of order n of the multiplier: $*k$ takes the cohort representing a given central element by ω to that representing it by ω^k.

We now turn to the column by column description of an ATLAS table.

12. The character number column(s)

In this column the rows containing characters are numbered $\chi_1, \chi_2, \chi_3, \ldots$ for easy reference. In wide tables this column is repeated at the left and right edges of the separate pages.

The reader is warned that in complicated situations a single row may represent several characters.

13. The indicator column for G, and for $m.G$

The Frobenius–Schur *indicator* function for a character χ of a group H may be defined as

$$\operatorname{ind}\chi = \frac{1}{|H|}\sum_{h\in H}\chi(h^2).$$

For an irreducible character χ we have

ind $\chi = 0$ if χ takes any non-real value
ind $\chi = +1$ if χ is afforded by a representation written over the reals
ind $\chi = -1$ for other real-value characters.

The *indicator column* uses the symbols ○, +, − for these three cases.

The rows corresponding to a triple or higher order multiple cover $m.G$ of G each represent $\phi(m)$ distinct characters related by algebraic conjugation. The character values are printed only for one of these characters, which serves as *proxy* for the others. A symbol ○2 or ○4 or ... indicates that the row in being used in this way to represent 2 or 4 or ... characters, all having indicator ○.

14. Columns for classes of G

The first detachment of columns has a column for each conjugacy class of G. Against the typical character χ_n of G it gives the value $\chi_n(g)$ for g in the given class. The notation for algebraic irrationalities has been explained. Thus from the $3A$ column of our example A_5, we read the five character values

$$\left.\begin{array}{l}\chi_1(g)=1\\ \chi_2(g)=0\\ \chi_3(g)=0\\ \chi_4(g)=1\\ \chi_5(g)=-1\end{array}\right\}\text{ giving the values of } A_5 \text{ characters at an element of order 3.}$$

If G has a multiple cover $m.G$, then g will be the image of m distinct elements $g_0, g_1, \ldots, g_{m-1}$ of $m.G$. The rows of the table corresponding to characters faithful on $m.G$ give character values only at g_0, since for these characters we have $\chi_n(g_i) = \omega^i\chi_n(g_0)$, where ω is a primitive mth root of unity. (It follows that $\chi_n(g_i)=0$ unless there are m distinct conjugacy classes g_i above g.) Thus in our example

$$\text{we read}\left\{\begin{array}{l}\chi_6(g_0)=-1\\ \chi_7(g_0)=1\\ \chi_8(g_0)=0\end{array}\right\}\text{ and deduce that}\left\{\begin{array}{l}\chi_6(g_1)=1\\ \chi_7(g_1)=-1\\ \chi_8(g_1)=0\end{array}\right\},$$

for the two inverse images g_0 and g_1 of an element g of class $3A$.

15. The detachment of columns for a group $G.2$

There are simple relations between the characters of G and $G.2$.

The splitting case
The first possibility is that a character χ of G may extend to $G.2$. It then necessarily does so in two ways, giving two characters χ^0 and χ^1 of $G.2$, whose values on elements of $G.2$ outside G are negatives of each other. In this case, we put the *splitting symbol* (:) in the fusion column, the indicators (+, −, or ○) of both χ^0 and χ^1 in the indicator column, and then the values of χ^0 (only) in the columns for classes of $G.2$ outside G.

Thus the row

	ind	1A	2A	3A	5A	5B	fus	ind	2B	4A	6A
χ_4	+	4	0	1	−1	−1	:++		2	0	−1

of our example means that χ_4 splits to yield two characters χ_4^0 and χ_4^1 of $G.2 = S_5$, with the same values as χ_4 on elements of A_5, and otherwise

$$\chi_4^0(2B)=2,\quad \chi_4^0(4A)=0,\quad \chi_4^0(6A)=-1,$$
$$\chi_4^1(2B)=-2,\quad \chi_4^1(4A)=0,\quad \chi_4^1(6A)=1.$$

Both χ_4^0 and χ_4^1 have indicator +.

The fusion case
The other possibility is that two characters χ_m and χ_n of G may fuse to give a single character $\chi_{m,n}$ of $G.2$, with values

$$\chi_{m,n}(g) = \chi_m(g) + \chi_n(g), \text{ for elements of } G$$
$$\chi_{m,n}(g) = 0, \text{ for elements of } G.2 \text{ outside } G.$$

We indicate this case by drawing a *fusion join* between dots against χ_m and χ_n in the fusion column, and then continuing only the first of these two rows into the $G.2$ detachment, with the indicator of $\chi_{m,n}$ in the indicator column, and the values (all 0) of $\chi_{m,n}$ on elements of $G.2$ outside G in the remaining columns of the $G.2$ detachment. Any class of G on which χ_m and χ_n take distinct values fuses with the class on which those values are taken in the other order to give a single class of $G.2$.

Thus from our example we read

	ind	1A	2A	3A	5A	5B	fus	ind	2B	4A	6A
χ_2	+	3	−1	0	$-b5$	*		+	0	0	0
χ_3	+	3	−1	0	*	$-b5$	|				

and deduce that these two characters fuse to give a single character of S_5 with values

	ind	1A	2A	3A	5AB = 5A ∪ 5B	2B	4A	6A
$\chi_{2,3}$	+	6	−2	0	$1 = -b_5 - b_5^*$	0	0	0

The complete character table for S_5 can now be read from our table. It is

	ind	1A	2A	3A	5AB	2B	4A	6A
χ_1^0	+	1	1	1	1	1	1	1
χ_1^1	+	1	1	1	1	−1	−1	−1
$\chi_{2,3}$	+	6	−2	0	1	0	0	0
χ_4^0	+	4	0	1	−1	2	0	−1
χ_4^1	+	4	0	1	−1	−2	0	1
χ_5^0	+	5	1	−1	0	1	−1	1
χ_5^1	+	5	1	−1	0	−1	1	−1

We remark that certain other symbols can appear in the fusion and indicator columns for a group $m.G.a$. They are explained in Section 18.

16. The detachment of columns for a group $G.a$, $a \geqslant 3$

For an automorphic extension $G.a$, where $a \geqslant 3$, we choose in $G.a$ one particular coset of G that generates $G.a$, and call this *the generator coset* for $G.a$. We do not print character values for the classes of $G.a$ lying in cosets that generate $G.a$ but are not the chosen generator coset, since each such class is an algebraic conjugate of a corresponding class in the generator coset, which we call its *proxy* class. The exact rules relating classes to their proxies will be described later. Classes lying in cosets that do not generate $G.a$ are regarded as pertaining to smaller extensions $G.a'$ $(a'<a)$.

Our conventions are the natural extensions of those for groups $G.2$, but more things can happen.

The splitting case
If a character χ of G extends to $G.a$, it does so in a ways, giving a characters $\chi^0, \chi^1, \ldots, \chi^{a-1}$ of $G.a$, whose values at elements of the generator coset are related by

$$\chi^i(g) = \omega^i\chi^0(g),$$

for a primitive ath root of unity ω. Such cases are indicated by the splitting symbol (:) in the fusion column, followed by the indicators for $\chi^0, \chi^1, \ldots, \chi^{a-1}$ (in that order) in the indicator

column, and then the values of χ^0 (only) in the remaining columns of the $G.a$ detachment.

The fusion case

It can happen that a characters $\chi_m, \chi_n, \ldots, \chi_p$ of G may fuse to give a single character $\chi_{m,n,\ldots,p}$ of $G.a$, with values $\chi_m + \chi_n + \ldots + \chi_p$ on G and 0 elsewhere. In this case, the fusion column contains a line joining dots against those characters, and only the earliest of the corresponding rows is continued further into the $G.a$ detachment of columns, by the indicator of $\chi_{m,n,\ldots,p}$ and its values (all 0) on the classes of the generator coset for $G.a$.

Mixed cases

If $a = a_1 a_2$ is composite, it can happen that each of a_2 particular characters of G may extend, as in the splitting case, to give a_1 characters of $G.a_1$, and that the resulting $a_1 a_2$ characters fuse in sets of a_2 to give a_1 characters of $G.a = (G.a_1).a_2$.

In this case our fusion column would contain a_2 joined copies of the splitting symbol (:), the earliest of which would be followed by the indicators of the a_1 resulting characters and their values (all 0) on the ensuing classes. In the case $a = 6$, $a_1 = 3$, $a_2 = 2$ this would look like:

```
   (G)        (G.2)          (G.3)        (G.6)
+ ~~~~~~ | + 0  0...0  : +∞ ~~~~~~ | +∞   0...0
+ ~~~~~~ |             : +∞ ~~~~~~ |
```

where ~~~~~~ indicates a line of character entries. We can regard this *either* as one character of $G.2$ splitting to become three of $G.6$, *or* as three pairs of characters of $G.3$, with each pair fusing to give a single character of $G.6$. Note that the fusion column always refers back to G, and that : means that there has been splitting somewhere on the way from G to $G.a$, while the joins similarly indicate that there has also been fusion somewhere along the way.

In the case $a = 4$, $a_1 = a_2 = 2$, the table would look like:

```
   (G)        (G.2)      (G.4)
+ ~~~~~~ : ++ ~~~~~~ | ++ 0...0
+ ~~~~~~ : ++ ~~~~~~ |
```

and can be regarded as two pairs of characters of $G.2$, each pair fusing to give a single character of $G.4$.

17. Follower cosets

We have already remarked that for any (cyclic) automorphic extension $G.a$, the corresponding detachment of columns of the ATLAS table refers only to the classes in its chosen generator coset, since the values for the other classes of $G.a$ can be deduced from these. If we printed one such detachment for each cyclic subgroup of the automorphism group of G, we should obtain what we call the Full Atlas Table (FAT) for G.

Although it is useful as a theoretical standard, the FAT table is usually too fat. We have thinned it out by selecting only one (*leader*) extension $G.a$ from each family of extensions equivalent under $Aut(G)$. The detachment of columns corresponding to the leader extension is printed in full, and followed by only the indicator and fusion columns for the remaining (*follower*) extensions equivalent to it.

18. The portion of an ATLAS table for a bicyclic extension $m.G.a$

For a bicyclic extension $m.G.a$ in which the central cyclic subgroup m of $m.G$ remains central, our conventions can best be described as the union of those for $m.G$ and $G.a$. The reader should be able to read off the characters of the group $2.G.2$ appropriate to our example $G = A_5$:

class:		$1A_0$	$1A_1$	$2A_0$	$3A_0$	$3A_1$	$5AB_0$	$5AB_1$	$2B_0$	$4A_0$	$4A_1$	$6B_0$	$6B_1$	
order:		1	2	4	3	6	5	10	2	8	8	6	6	
χ_1^0	+	1	1	1	1	1	1	1	1	1	1	1	1	
χ_1^1	+	1	1	1	1	1	1	1	−1	−1	−1	−1	−1	
$\chi_{2,3}$	+	6	6	−2	0	0	1	1	0	0	0	0	0	
χ_4^0	+	4	4	0	1	1	−1	−1	2	0	0	−1	−1	
χ_4^1	+	4	4	0	1	1	−1	−1	−2	0	0	1	1	
χ_5^0	+	5	5	1	−1	−1	0	0	1	−1	−1	1	1	
χ_5^1	+	5	5	1	−1	−1	0	0	−1	1	1	−1	−1	
$\chi_{6,7}$	−	4	−4	0	−2	1	−1	1	0	0	0	0	0	−
χ_8^0	○	4	−4	0	1	−1	−1	1	0	0	0	i_3	$-i_3$	−
χ_8^1	○	4	−4	0	1	−1	−1	1	0	0	0	$-i_3$	i_3	−
χ_9^0	○	6	−6	0	0	0	1	−1	0	i_2	$-i_2$	0	0	−
χ_9^1	○	6	−6	0	0	0	1	−1	0	$-i_2$	i_2	0	0	−
									4	8	8	12	12	

However, you are just as likely to want the characters of the isoclinic variant, also of structure $2.G.2$. To obtain this, multiply (or divide) all the numbers in the boxed portion by i, and use the new orders of elements given below the box, and the new indicators given to the right of it. For the definition of isoclinism, and the rules for computing these new orders and indicators, see Chapter 6, Section 7.

A character of $m.G$ for which we printed the indicator symbol $\circ N$ is the chosen proxy from a set of N algebraically conjugate characters, as we described in Section 8. It is possible that each of these extends to give a characters of $m.G.a$ (see 'the splitting case' in Section 15 or Section 16).

In such a case, we put the symbol $\circ\circ\ldots\circ N$ (with a symbols $\circ$) in the indicator column for $m.G.a$. In general a string of k indicator symbols +, −, ○ followed by a number N indicates that the printed character yields k characters of the given indicators upon multiplication by linear characters of the appropriate group, and that each of these is proxy for a family of N algebraically conjugate characters which have distinct values when restricted to the central cyclic subgroup m of $m.G$.

When the automorphism of the extending cyclic group a acts non-trivially on m, new symbols can also appear in the fusion column for $m.G.a$. The symbols

$$\Big|_{*k}$$

appearing in this column against characters χ_p and χ_q from a given cohort C mean that χ_p fuses with the character in the algebraically conjugate cohort C^{*k} whose proxy is χ_q. The symbol

$$*k$$

in the fusion column against character χ_p means that χ_p fuses with the character in C^{*k} whose proxy is χ_p itself. The algebraic conjugation symbol $*k$ in this may be replaced by any of $**k$, $**$, or $*$.

19. The precise rules for proxy classes and characters

We have already remarked that we print values for classes in only one of the cosets of G generating a given upward cyclic extension $G.a$, and for characters in only one of the cohorts that realize a given cyclic quotient of the multiplier. For most purposes it is unnecessary to select any particular correspondence between the retained objects and the omitted ones, which are merely their algebraic conjugates. However, a particular correspondence is used to give a precise meaning to our power maps and fusion markers.

Suppose we want to find the classes of a coset C^k for which a given class in the printed coset C serves as proxy, where $C^n = G$. If g is any element of the given class, these classes are those of certain powers $g^{k'}$ of g, where it is only necessary to specify the numbers k' modulo the order N of the element g. In the vast majority of cases in this ATLAS, n divides 12, and we specify k' by the congruences:

$k' \equiv k$ modulo n,
$k' \equiv \pm 1$ modulo powers of 2 and 3 dividing N,
$k' \equiv +1$ modulo any divisor of n prime to 2 and 3.

The only other case that actually appears in this ATLAS is for $n=5$. In this case, we specify k' by

$k' \equiv k$ modulo 5,
k' is of order dividing 4 modulo powers of 5 dividing N,
$k' \equiv +1$ modulo any divisor of n prime to 5.

These conventions are the simplest ones that ensure that the algebraic conjugation $*k'$ has the correct effect on nth roots of unity, while fixing 'irrelevant' irrationalities. Any rule that extends this to all numbers n must be to some extent arbitrary.

The rule for proxy characters is precisely similar. The characters in the cohort C^{*k} for which a given character χ from the cohort C serves as proxy are the algebraically conjugate characters $\chi^{*k'}$, where k' is determined just as above from n, the order of the cyclic quotient of the multiplier realized faithfully by χ, and any number N for which the values of χ lie in the field of Nth roots of unity.

20. Abbreviated character tables

There are some groups whose character tables seemed to deserve compression before we felt able to justify their inclusion. In these cases, indicated by the phase 'Abbreviated character table', we have printed just one representative from each algebraically conjugate family of classes or characters.

An entry of form N/D in the centralizer order row indicates that the corresponding class is the only printed member of an algebraically conjugate family of D classes, each of centralizer order N. Such a family behaves in many ways like a single conjugacy class with centralizer order $\frac{N}{D}$. The entry in the class name row consists of the order n of the elements concerned, followed by the tag letters of the first and last classes in the family. The remaining entries in the appropriate column refer only to the first class in the family.

So in our table for $L_3(8)$ (page 74), the column beginning

```
   @
3528/6
   A
   A
 7AF
```

refers to class $7A$, and tells us that this class is the only printed representative of the 6 classes $7A$, $7B$, $7C$, $7D$, $7E$, $7F$, all having centralizer order 3528.

A row beginning $+M$, $\circ M$, or $-M$ indicates that the printed character is the only printed representative of an algebraically conjugate family of M characters, all having the appropriate indicator + or $\circ$ or $-$. Thus the last row of the table for $L_3(8)$ begins +3, indicating that the printed character is one of an algebraically conjugate family of 3 characters, all having indicator +.

The complete table, except possibly for a small amount of the power map information, can be recovered by applying all possible algebraic conjugations to the printed classes and characters.

8

Concluding remarks

We have given a great deal of thought to the arrangement and printing of character tables, and here pass on our observations to potential table compilers who wish to adopt our conventions.

1. Format

Tables with columns of randomly varying widths have a 'ragged' appearance which is very wearying to the reader. In our tables the only permitted widths are 4, 6, 8, . . . spaces. We have taken great pains, particularly with our irrationality conventions, to ensure that most columns will fit into the standard width of 4 spaces, so that large tracts of table have a regular layout. The even-width requirement entails that a wider column is *seen* to be wider—columns whose widths are nearly but not quite equal produce a slightly disorienting effect.

The rows are usually at double line spacing, but have been compressed to one-and-a-half line spacing for a few large tables. The interline spaces dramatically increase legibility, and produce a pleasingly square appearance.

2. Ordering of classes and characters

Many table compilers arrange the conjugacy classes in an order which to some extent reflects the power maps. Thus a class whose elements have prime order p may be followed by classes containing elements of orders $2p$, $3p$, etc., having powers in the original class. The merits of such arrangements are usually more evident to the compiler than the user, who is seldom properly informed about the principles (if any) of the arrangement, and so cannot use the implied power map information. It is better to choose a simpler arrangement, and explicitly indicate the power maps.

In this ATLAS, the conjugacy classes within a given coset are arranged

firstly, by increasing succession of n, the order of their elements;

secondly, for elements with the same n, by decreasing succession of N, their centralizer order;

thirdly, for elements with the same n and N, by increasing succession of d, the degree of the algebraic number field generated by their character values (so that rational elements come first); and

fourthly, for elements with the same n, N, and d, in a manner which seems best compatible with the p' parts, so that, other things being equal, we prefer to arrange elements of order 10 in the same succession as the elements of order 5 that are their odd parts.

Again, the characters within a given cohort are arranged

firstly, in increasing succession of n, their character degree;

secondly, for characters with the same n, in increasing succession of d, the degree of the number field generated by their values;

thirdly, for characters with the same n and d, so that characters that fuse in some automorphic extension group are close together; and

fourthly, so that the resulting blocks of algebraic irrationalities have a readily visible structure.

Of course *any* system of this kind has the merit that if two investigators use the same system for the same group, their character tables will be almost identical. [We do *not* think it would be sensible to make the system so precise that it would only permit one arrangement per group.] Our system tends to put the 'important' elements first, and makes it likely that the conjugacy classes in a subgroup will be in roughly the same order as those in the containing group.

Similar remarks hold for characters. The ordering by degrees is useful in discussions of the possible decompositions of some compound character, and often makes it easier to identify the restriction of a character to a subgroup.

3. Some other 'virtuous' properties

When tabulating characters of a group $M.G$ (or $M.G.A$) with a large multiplier, we have always arranged that for any given g, the displayed pre-images of g in all the cyclic extensions $m.G$ are all images of a 'universal' pre-image of g in $M.G$. 'Dually', we have arranged *whenever possible* that the prolongations of a given character to all the cyclic extensions $G.a$ are restrictions of a 'universal' character defined on $G.A$.

There are still some choices that are more virtuous than others. For example in a group of structure $2^2.G.3$, in which the three involutions of the normal fourgroup are permuted by the automorphism group, only one of the four pre-images of a given element can be invariant under an outer automorphism; this should be the printed 'universal' pre-image. 'Dually', in a group of structure $G.2^2.3$ in which the outer automorphism group is A_4, a character of G which extends to $G.2^2$ does so in four ways, only one of which can be invariant under the additional automorphisms; this character should be the printed one. In groups with complicated multiplier and automorphism group such desiderata can conflict, so we do not regard them as obligatory (and the reader cannot rely on them). But a table which satisfies them is more useful than one that does not, since there is a higher probability that the element the reader wants is exactly that which is tabulated.

4. The reliability of ATLAS information

> With regard to errors in general, whether falling under the denomination of mental, typographical, or accidental, we are conscious of being able to point to a greater number than any critic whatever. Men who are acquainted with the innumerable difficulties attending the execution of a work of such an extensive nature will make proper allowances. To these we appeal, and shall rest satisfied with the judgement they pronounce.
>
> *Preface to the first edition of the Encyclopaedia Brittanica, 1771*

Our fairly wide experience has taught us that published character tables are as likely as not to contain errors (which are usually minor). We have been able to correct errors in our own tables up to a very late date before publication, but the rate of their discovery suggests that the above quotation will become apposite a few months after the ATLAS appears in print.

We first briefly comment on the information *not* contained in the character tables. Experts will know that one of the most common errors in group-theoretical papers is for the structure of

a group to be slightly mis-stated. We hope and believe that our own error rate in this respect is rather smaller than the average, but since the ATLAS makes very many more assertions about group structures than any other work, we are certain that they will not all be exactly correct. We can only counsel the reader who feels he may have discovered an error to check the consistency of the statement he doubts with similar statements about subgroups or with analogous cases.

Although we intended at first to subject all our tables to a large battery of computer tests, we must confess that in the event the only such test that has been consistently applied to every table is the orthogonality check. (There are many other mechanical tests that could be easily applied to ordinary tables, but for which the complexity of applying them to our compound tables has defeated us.) We are confident that the overall error rate in our character tables is very low indeed, but feel that the reader should be aware of the possibility that there are occasional errors, and of their most likely form. To put the problem in perspective, we emphasize again the very large amount of information that this ATLAS contains. If, for example, we were to misprint one in every thousand digits, then the MONSTER character table alone would contain about 100 errors. Our actual error rate is a few orders of magnitude smaller!

If you suspect an error, perhaps the first thing to do is to check that you have not misunderstood the ATLAS conventions, which are sometimes subtler than you may think. Then for:

centralizer orders: check that the given number is the sum of the squares of the moduli of the entries in its column;

power maps and p′ parts: check the mutual consistency of these, for instance using $(x^2)^3=(x^3)^2$, and check the congruence $\chi(g)\equiv\chi(g')$ modulo p, whenever g' is the p' part of g, and χ takes rational values on both. (For irrational values, the modulus is $1-z_p$.)

lifting orders: check consistency with power maps—also the above congruences;

indicators: the indicator should be 0 just if some character value is non-real; also, check the formulae

$$\mathrm{ind}(\chi)=\frac{1}{|G|}\sum_g \chi(g^2) \quad \text{and} \quad R(g)=\frac{1}{|G|}\sum_\chi \mathrm{ind}(\chi)\,.\,\chi(g)$$

where $R(g)$ is the number of square roots of g;

fusion: check that $G\,.\,a$ has the same number of classes as characters, also check compatibility with indicators.

We have discussed these first since our experience suggests that it is this 'peripheral' information that is most likely to be at risk. The character values themselves are much safer.† Any error that remains in them probably concerns an irrational entry, or is an incompatibility between the tables for G and $G\,.\,a$.

An extremely valuable test which we recommend when the above simple rules of thumb have failed is to compute the skew squares

$$\chi^{2-}(g)=\frac{(\chi(g))^2-\chi(g^2)}{2}$$

of one or more characters χ, and check their inner products with selected irreducibles. One should also check the consistency of restriction maps from groups to subgroups whose tables are also known.

Of course it can be a good idea to check a doubtful point against another published table, which might well be the one from which ours was originally derived. A disagreement *probably* means that we believed we had found and corrected an error in the source table, but of course we could be wrong, or could have inadvertently introduced some error ourselves.

If you do discover and confirm an error, please write to us about it!

† Any complacency we might have had in this regard was rudely shattered when the pre-publication version of the table for the outer automorphism group of the Held group was found to contain an error affecting 22 entries (but obeying the orthogonality conditions)! A similar, but much smaller, error was discovered in the table for the outer automorphism group of J_3.

5. Acknowledgements

This is perhaps the place for a comment about references and the bibliography. Our entries for the individual groups contain no explicit references to sources. This is because the few lines we allot to any given construction often contain material culled from many places (sometimes barely remembered) which might have been transformed beyond recognition by our own investigations or transliterations. We intend no disrespect, and beg forgiveness for any offence our policy has caused. We gratefully acknowledge here that we have used information from many published and unpublished sources that are not explicitly referenced in this volume.

The bibliography on pp. 243–51 is restricted to the 26 sporadic groups, and to a number of books and papers which give information about most or all of the infinite families of simple groups. The works by Gorenstein and Davis in the latter portion are very much more extensive bibliographies.

It is a pleasure to record our indebtedness to many colleagues throughout the world who have freely sent us information. We mention particularly our major sources of character tables:

M. Hall, Jr	[the Tits group, $6A_6$, $6A_7$, . . .]
Zia-ud-Din	[S_{12}, S_{13}]
A. O. Morris	[$2S_n$]
J. A. Todd	[the Mathieu groups, $U_4(3)$, . . .]
D. Enomoto	[$G_2(q)$]
H. N. Ward	[${}^2G_2(q)$]
B. Srinivasan	[$S_4(q)$]
J. McKay and D. Wales	[$3J_3$; and other assistance]
D. Gabrysch	[$F_4(2)$, ${}^2E_6(2)$, . . .]
D. C. Hunt	[many, including the Baby Monster]
J. S. Frame, A. Rudvalis, and collaborators	[many, including $O_n(2)$]
B. Fischer, D. Livingstone, M. Thorne	[the Monster],

and finally the Aachen 'CAS' team led by J. Neubüser and H. Pahlings both for many original tables and for improvements, extensions, and corrections to many others.

Among our group-theoretical colleagues at Cambridge who have used the ATLAS and contributed tables, corrections, improvements, or criticism are David Benson, Patrick Brooke, Mike Guy, David Jackson, Gordon James, Peter Kleidman, Martin Liebeck, Nick Patterson, Larissa Queen, Alex Ryba, Jan Saxl, Peter Smith, and finally John Thompson, who has acted as our friend and mentor throughout.

We owe a particular debt to Jonathan Thackray, who designed and wrote the computer system in which our compound character tables are held. Many errors were discovered and eliminated as a result of his work. We thank Leonard Soicher for his valuable work which produced the Coxeter-type presentations displayed for many groups in this ATLAS.

The authors' names appear on the cover of this ATLAS in what is both the alphabetical order and the chronological order of their involvement with the ATLAS project. Here are some comments about their individual roles:

Robert Curtis and I started the work by designing the ATLAS format and converting many pre-existing tables into it. Curtis also made many investigations into the subgroup structure and primitive permutation representations of various groups, not all of which work has been used in this volume.

Simon Norton constructed the tables for a large number of extensions, including some particularly complicated ones. He has throughout acted as 'troubleshooter'—any difficult problem was automatically referred to him in the confident expectation that it would speedily be solved.

Richard Parker was responsible for the initial 'mechanization' of the ATLAS project, and also did a great part of the more tedious job of entering pre-existing tables into the computer. He has also computed a large number of modular character tables, intended for a later ATLAS publication.

Robert Wilson has investigated, and often completely enumerated, the maximal subgroups of a large number of ATLAS groups. He has greatly increased the usefulness of this ATLAS by adding this and other information, and over the last few years has cheerfully shouldered the enormous task of gathering and transforming our untidy heaps of material into a form fit for publication.

My own function was to initiate and control the entire project, to collaborate with each of the above, and (eventually) to write this *Introduction.* *John Conway*

Constructions

Linear (2) $GL_3(2) \cong PGL_3(2) \cong SL_3(2) \cong PSL_3(2) \cong G$: all non-singular 3 x 3 matrices over $\mathbf{F}_2$;

the points and lines of the corresponding projective plane can be numbered (mod 7) so that $L_i = \{P_{i+1}, P_{i+2}, P_{i+4}\}$;

G.2 is obtained by adjoining the duality (graph) automorphism

Linear (7) $GL_2(7) \cong 3 \times 2.G.2$: all non-singular 2 x 2 matrices over $\mathbf{F}_7$;

$PGL_2(7) \cong G.2$; $SL_2(7) \cong 2.G$; $PSL_2(7) \cong G$

Unitary $GU_2(7) \cong 2.(G \times 4).2$: all 2 x 2 matrices over $\mathbf{F}_{49}$ preserving a non-singular Hermitian form;

$PGU_2(7) \cong G.2$; $SU_2(7) \cong 2.G$; $PSU_2(7) \cong G$

Orthogonal $GO_3(7) \cong 2 \times G.2$: all 3 x 3 matrices over $\mathbf{F}_7$ preserving a non-singular quadratic form;

$PGO_3(7) \cong SO_3(7) \cong PSO_3(7) \cong G.2$; $O_3(7) \cong G$

Reflection $G \times 2$: symmetries of the lattice Λ_3^{b7} whose minimal (root) vectors are : $(\pm2,0,0)^S$, $(0,\pm b7,\pm b7)^S$, $(\pm1,\pm1,\pm b7^{**})^S$;

the group is generated by reflections in these vectors;

G : the symmetries of determinant 1

Vectors 2G : the symmetries of the set of 8 (±)vectors (where b=b7, p=i7) :

$v_\infty=(p;0,0,0)$ $v_0=(-1;b,b,b)$ $v_1=(-1;b,0,b^2)$ $v_2=(-1;0,b^2,b)$ $v_3=(-1;2,b,0)$ $v_4=(-1;b^2,b,0)$ $v_5=(-1;0,2,b)$ $v_6=(-1;b,0,2)$;

these generate the laminated lattice $\Lambda_{4,b7}$, whose full automorphism group is $2A_7$

Presentations $G \cong (3,3|4,4) \cong (2,3,7;4) \cong \langle S,T | S^7=(S^4T)^4=1,(ST)^3=T^2[=1]\rangle$;

$G.2 \cong G^{3,7,8} \cong (2,3,8;4)$; $2 \times G.2 \cong G^{3,8,8}$

$A_6 \cong L_2(9) \cong S_4(2)'$

Alternating group A_6; Linear group $L_2(9) \cong A_1(9) \cong U_2(9) \cong S_2(9) \cong O_3(9) \cong O_4^-(3)$;

Derived symplectic group $S_4(2)' \cong C_2(2)' \cong O_5(2)'$

Order = 360 = $2^3.3^2.5$ Mult = 6 Out = 2^2

Constructions

Alternating $S_6 \cong G.2_1$: all permutations on 6 letters;

$A_6 \cong G$: the even permutations; 2.G and $2.G.2_1$: the Schur double covers

The outer automorphism of S_6 interchanges the 15 duads ab (pairs) with the 15 synthemes ab.cd.ef (trisections), so interchanges the 6 points a (which could be specified by 5 duads ab, ac, ad, ae, af) with the 6 totals (sets of 5 synthemes containing all duads)

Linear $GL_2(9) \cong 2.(G \times 4).2_2$: all 2 x 2 non-singular matrices over $\mathbf{F}_9$;

$PGL_2(9) \cong G.2$; $SL_2(9) \cong 2.G$; $PSL_2(9) \cong G$;

$\Gamma L_2(9) \cong 2.(G \times 4).2^2$; $P\Gamma L_2(9) \cong G.2^2$; $\Sigma L_2(9) \cong 2.G.2_1$; $P\Sigma L_2(9) \cong G.2_1$

Unitary $GU_2(9) \cong 5 \times 2.G.2_2$: all matrices over $\mathbf{F}_{81}$ preserving a non-singular Hermitian form;

$PGU_2(9) \cong G.2_2$; $SU_2(9) \cong 2.G$; $PSU_2(9) \cong G$

Orthogonal (9) $GO_3(9) \cong 2 \times G.2_2$: all 3 x 3 matrices over $\mathbf{F}_9$ preserving a non-singular quadratic form;

$PGO_3(9) \cong SO_3(9) \cong PSO_3(9) \cong G.2_2$; $O_3(9) \cong G$; $\Gamma O_3(9) \cong 2 \times G.2^2$; $P\Gamma O_3(9) \cong \Sigma O_3(9) \cong P\Sigma O_3(9) \cong G.2^2$

Orthogonal (3) $GO_4^-(3) \cong 2 \times G.2_1$: all 4 x 4 matrices over $\mathbf{F}_3$ preserving a quadratic form of Witt defect 1, for example $x_1^2 + x_2^2 + x_3^2 - x_4^2$; $PGO_4^-(3) \cong G.2_1$; $SO_4^-(3) \cong 2 \times G$; $PSO_4^-(3) \cong O_4^-(3) \cong G$;

by taking the 4-space of the vectors (x_i) in $\mathbf{F}_3^6$ with $\Sigma x_i=0$, modulo (111111), we see the isomorphism with $2 \times S_6$

Orthogonal (2) $GO_5(2) \cong PGO_5(2) \cong SO_5(2) \cong PSO_5(2) \cong G.2_1$: all 5 x 5 matrices over $\mathbf{F}_2$ preserving a non-singular quadratic form; $O_5(2) \cong G.2_1$

Symplectic $S_4(2) \cong G.2_1$: all 4 x 4 matrices over $\mathbf{F}_2$ preserving a non-singular symplectic form;

Mathieu $M_{10} \cong G.2_3$: the stabilizer of a point in M_{11}, or two points in M_{12};

in M_{24} the subgroups of $M_{10}.2 \cong G.2^2$ have orbits as follows:

G (1,1,10;6,6), $G.2_1$ (2,10;6,6), $G.2_2$ (2,10;12), $G.2_3 \cong M_{10}$ (1,1,10;12)

Hexacode 3.G : the monomial symmetries of the code over $\mathbf{F}_4 = \{0,1,w,\bar{w}\}$ whose 64 = 36+12+9+6+1 words are obtained from (0a 0a bc) (36), (bc bc bc) (12), (00 aa aa) (9), (aa bb cc) (6), (00 00 00) (1) (in which a,b,c is any cyclic permutation of $1,w,\bar{w}$) by bodily permuting the 3 couples, and/or reversing any 2 of them;

the words of weight 6 (total words) are permuted (modulo scalar factors) like the 6 totals of 5 disjoint synthemes

Reflection 2 x 3.G : the symmetries of the $(\pm w)$vectors $(\pm 2,0,0)^S$, $(\pm 1,\pm 1,\pm \bar{h})^S$, $(0,\pm h,\pm h)^S$, $(\pm 1,\pm wc,\pm \bar{w}b)^S$ (where w = z3, b = b5, c = b5*, h = z3 - b5); the group is generated by the 45 reflections in these vectors

Quaternionic 2.G : the symmetries of the (i,w)vectors $(\theta,0)$, $((i+1)w^a,w^b)$, $(w^a,(i-1)w^b)$ where θ and i are quaternions with $\theta^2 = -3$, $i^2 = -1$, $\theta i = -i\theta$, and $2w = -1+\theta$; the group is generated by the 20 quaternionic reflections in these vectors - these reflections have order 3

Presentations $G \cong (3,4,5;2) \cong (5,5|2,4) \cong \langle x_1,x_2,x_3,x_4 | x_i^3=(x_ix_j)^2=1\rangle$;

$G.2_1 \cong$ ——•——•——•—— ; $2 \times G.2_2 \cong G^{4,5,8}$

A_7

Alternating group A_7

Order = 2,520 = $2^3.3^2.5.7$ Mult = 6 Out = 2

Constructions

Alternating $S_7 \cong G.2$: all permutations of 7 letters;

$A_7 \cong G$: the even permutations; 2.G and 2.G.2 : the Schur double covers

Lattice $2A_7 \cong 2.G$: the symmetries of the lattice $\Lambda_{4,b7}$ whose minimal vectors are obtained from ±(i7;0,0,0) ±(0;i7,0,0) ±(1;x,y,z) ±(-x;1,y,-z) ±(-xy;1,1,1) ±(1;xy,1,-1) ±(xy;0,z,1) ±(-x;yz,0,-1) ±(-1;0,xy,z) ±(0;1,-x,yz) by replacing each of x,y,z by one of b7 or b7**, and cyclically permuting the last 3 coordinates

Vectors $3A_7$: symmetries of the 21 (w)vectors obtained from (20 00 00), (00 11 11), (01 01 $w\bar{w}$) by bodily permuting the 3 couples, and reversing any 2 couples (see A_6 (hexacode));

the lattice these generate has automorphism group $6U_4(3).2$ (see $U_4(3)$)

Unitary $3A_7$ has a 3-dimensional unitary representation over $\mathbb{F}_{25}$ (see $U_3(5)$)

Presentations $G \cong \langle A,B \mid A^4=B^5=(AB)^3=(A^{-1}BA^2B^2)^2=1\rangle \cong \langle x_1,\ldots,x_5 \mid x_i^3=(x_ix_j)^2=1\rangle$;

$G.2 \cong$ ———————— $\cong \langle A,B \mid A^2=[A,B^2]^2=[A,B^3]^2=1;B^7=(AB)^6\rangle$

$L_3(3)$

Linear group $L_3(3) \cong A_2(3)$

Order = 5,616 = $2^4.3^3.13$ Mult = 1 Out = 2

Constructions

Linear $GL_3(3) \cong 2 \times G$: all 3 x 3 non-singular matrices over $\mathbf{F}_3$;

$SL_3(3) \cong PGL_3(3) \cong PSL_3(3) \cong G$; the points and lines of the corresponding projective plane can be numbered (mod 13) so that $L_i = \{P_i, P_{i+1}, P_{i+3}, P_{i+9}\}$;

G.2 is obtained by adjoining the duality (graph) automorphism

Presentation: $G \cong \langle S,T \mid S^6=T^3=(ST)^4=(S^2T)^4=(S^3T)^3=[S^2,(TS^2T)^2]=1\rangle$

$U_3(3) \cong G_2(2)'$

Unitary group $U_3(3) \cong {}^2A_2(3)$; Derived Chevalley group $G_2(2)'$

Order = 6,048 = $2^5.3^3.7$ Mult = 1 Out = 2

Constructions

Unitary $GU_3(3) \cong 4 \times G$: all 3×3 matrices preserving a non-singular Hermitian form over $\mathbf{F}_9$;

$PGU_3(3) \cong SU_3(3) \cong PSU_3(3) \cong G$

Chevalley $G_2(2) \cong G.2$: adjoint Chevalley group of type G_2 over $\mathbf{F}_2$;

G.2 : the automorphism group of a generalized hexagon of order (2,2) consisting of 63 vertices and 63 edges, each object being incident with 3 of the other type.

Cayley (2) G.2 : the automorphism group of the $\mathbf{F}_2$ Cayley algebra, whose elements are integral Cayley numbers modulo doubles of integral Cayley numbers (see below). A pair $\{x,y\} \neq \{0,1\}$ of elements with $x+y = 1$ is either <u>isotropic</u> with $x^2=y^2=0$ (36 cases), <u>non-isotropic</u> with $x^3=y^3=1$ (28), or <u>mixed</u> with $x^2=0$, $y^2=1$, or vice versa (63).

G.2 : the fixed points of $O_8^+(2)$ under its triality automorphism

Cayley ($\mathbb{Z}$) G.2 : the automorphism group of the integral Cayley algebra in which $i_\infty=1$, $i_{n+1}=i$, $i_{n+2}=j$, $i_{n+4}=k$ define a quaternion subalgebra for each n (subscripts modulo 7); $\sum x_n i_n$ is <u>integral</u> provided that all $2x_n$ are integral and the set of n for which x_n is integral is one of

{0124}, {0235}, {0346}, {0156}, {∞013}, {∞026}, {∞045}, {∞0123456} or their complements.

Alternatively, they can be generated by the even sums of X_∞, X_0, ... X_6 together with $1 = \sum X_n$, with multiplication defined by the equations $2X_n^2 = X_n-1$, $2X_0X_\infty = 1-X_1-X_2-X_4$, $2X_\infty X_0 = 1-X_3-X_5-X_6$ and their images under the coordinate permutation group $L_2(7)$.

Quaternionic $2 \times G$: the group generated by the 63=3+12+48 quaternionic reflections in the vectors $(2,0,0)^S$ (3), $(0,a,a)^S$ (12), and $(\bar{a},1,1)^S$ (48) and their images under $\mathrm{diag}(\pm1,\pm i,\pm i)^S$, where $2a = -1-i-\sqrt{5}j+k$

Presentation $G.2 \cong \langle \overset{a}{\bullet}\!\!-\!\!\overset{b}{\bullet}\!\!-\!\!\overset{c}{\bullet}\overset{8}{}\overset{d}{\bullet}\!\!-\!\!\overset{e}{\bullet} \mid a=(cd)^4,(bcde)^8=1 \rangle$

M_{11} and $L_2(27)$

Sporadic Mathieu group M_{11}

Order = 7,920 = $2^4.3^2.5.11$ Mult = 1 Out = 1

Constructions

11-point $G \cong M_{11}$: stabilizer of a point in M_{12};
the automorphism group of the Steiner system S(4,5,11);
automorphisms of the ternary Golay code C_{12} that fix a coordinate

12-point $G \cong M_{11}$: stabilizer of a total in M_{12};
automorphisms of the ternary Golay code C_{12} that fix a weight 12 word (total word);
in particular, the coordinate permutations that fix the set of 22 words obtained from
±(-;++-+++---+-) by cyclic permutations of the last 11 coordinates

Presentations $G \cong \langle A,B,C \mid A^{11}=B^5=C^4=(AC)^3=1, A^B=A^4, B^C=B^2 \rangle \cong \langle$  $\mid (ce)^2=a,\ [(abc)^5=1] \rangle$

$A_8 \cong L_4(2)$

Alternating group A_8; Linear group $L_4(2) \cong A_3(2) \cong O_6^+(2)$

Order = 20,160 = $2^6.3^2.5.7$ Mult = 2 Out = 2

Constructions

Alternating $S_8 \cong G.2$: all permutations on 8 letters;

$A_8 \cong G$: all even permutations; 2.G and 2.G.2 : the Schur double covers

Linear $GL_4(2) \cong PGL_4(2) \cong SL_4(2) \cong PSL_4(2) \cong G$: all non-singular 4 x 4 matrices over $\mathbf{F}_2$;

the points P_i and planes Q_i of the corresponding projective 3-space can be numbered (mod 15) so that

$Q_i = \{P_i, P_{i+5}, P_{i+10}, P_{i+1}, P_{i+2}, P_{i+4}, P_{i+8}\}$;

G.2 is obtained by adjoining the duality (graph) automorphism, interchanging points and planes

Orthogonal $GO_6^+(2) \cong PGO_6^+(2) \cong SO_6^+(2) \cong PSO_6^+(2) \cong G.2$: all 6 x 6 matrices over $\mathbf{F}_2$ fixing a quadratic form of Witt defect 0, for example $x_1x_2 + x_3x_4 + x_5x_6$; $O_6^+(2) \cong G$;

by taking the 6-space to be the even weight vectors in $\mathbf{F}_2^8$ modulo (11111111), with form equal to half the weight, we see the isomorphism with S_8

Mathieu G : the stabilizer in M_{24} of an octad and a point outside it; the group acts as A_8 on the octad, and $L_4(2)$ on its complement

Presentations G.2 ≅ ——————————— ; $G \cong \langle x_1,\ldots,x_6 \mid x_i^3=(x_ix_j)^2=1\rangle$

$L_3(4)$

Linear group $L_3(4) \cong A_2(4)$

Order = 20,160 = $2^6.3^2.5.7$ **Mult** = 4 x 4 x 3 **Out** = 2 x S_3

Constructions

Linear $GL_3(4) \cong 3.G.3$: all non-singular 3 x 3 matrices over $\mathbb{F}_4$;

$PGL_3(4) \cong G.3$; $SL_3(4) \cong 3.G$; $PSL_3(4) \cong G$;

$G.2_3$ etc. are obtained by adjoining the duality (graph) automorphism;

$\Gamma L_3(4) \cong 3.G.3.2_2$; $P\Gamma L_3(4) \cong G.3.2_2$; $\Sigma L_3(4) \cong 3.G.2_2$; $P\Sigma L_3(4) \cong G.2_2$

Mathieu $M_{21}.S_3 \cong G.3.2_2$: the set-stabilizer of a triad in M_{24}; $M_{21} \cong G$: the pointwise stabilizer;

the remaining 21 points form the projective plane whose lines are the 21 pentads which complete the triad to an octad

Lattice $6.G.2_1$ stabilizes the complex lattice Λ_6^{z3}, whose full automorphism group is $6U_4(3).2$ (see $U_4(3)$)

Presentation $12_2.G.2_3 \cong \langle$  $\mid (be)^2=(cde)^5, d=(ab)^4, 1=[e,(cbaba)^5] \rangle$

The multiplier M is generated by elements a,b,c,d satisfying $abc = a^4 = b^4 = c^4 = d^3 = 1$. The table shows how these are transformed by elements in the printed cosets and represented by characters in the printed cohorts. There is an automorphism acting as (abc)(d) on M, and as (XX'X") on cosets and cohorts.

coset						cohort

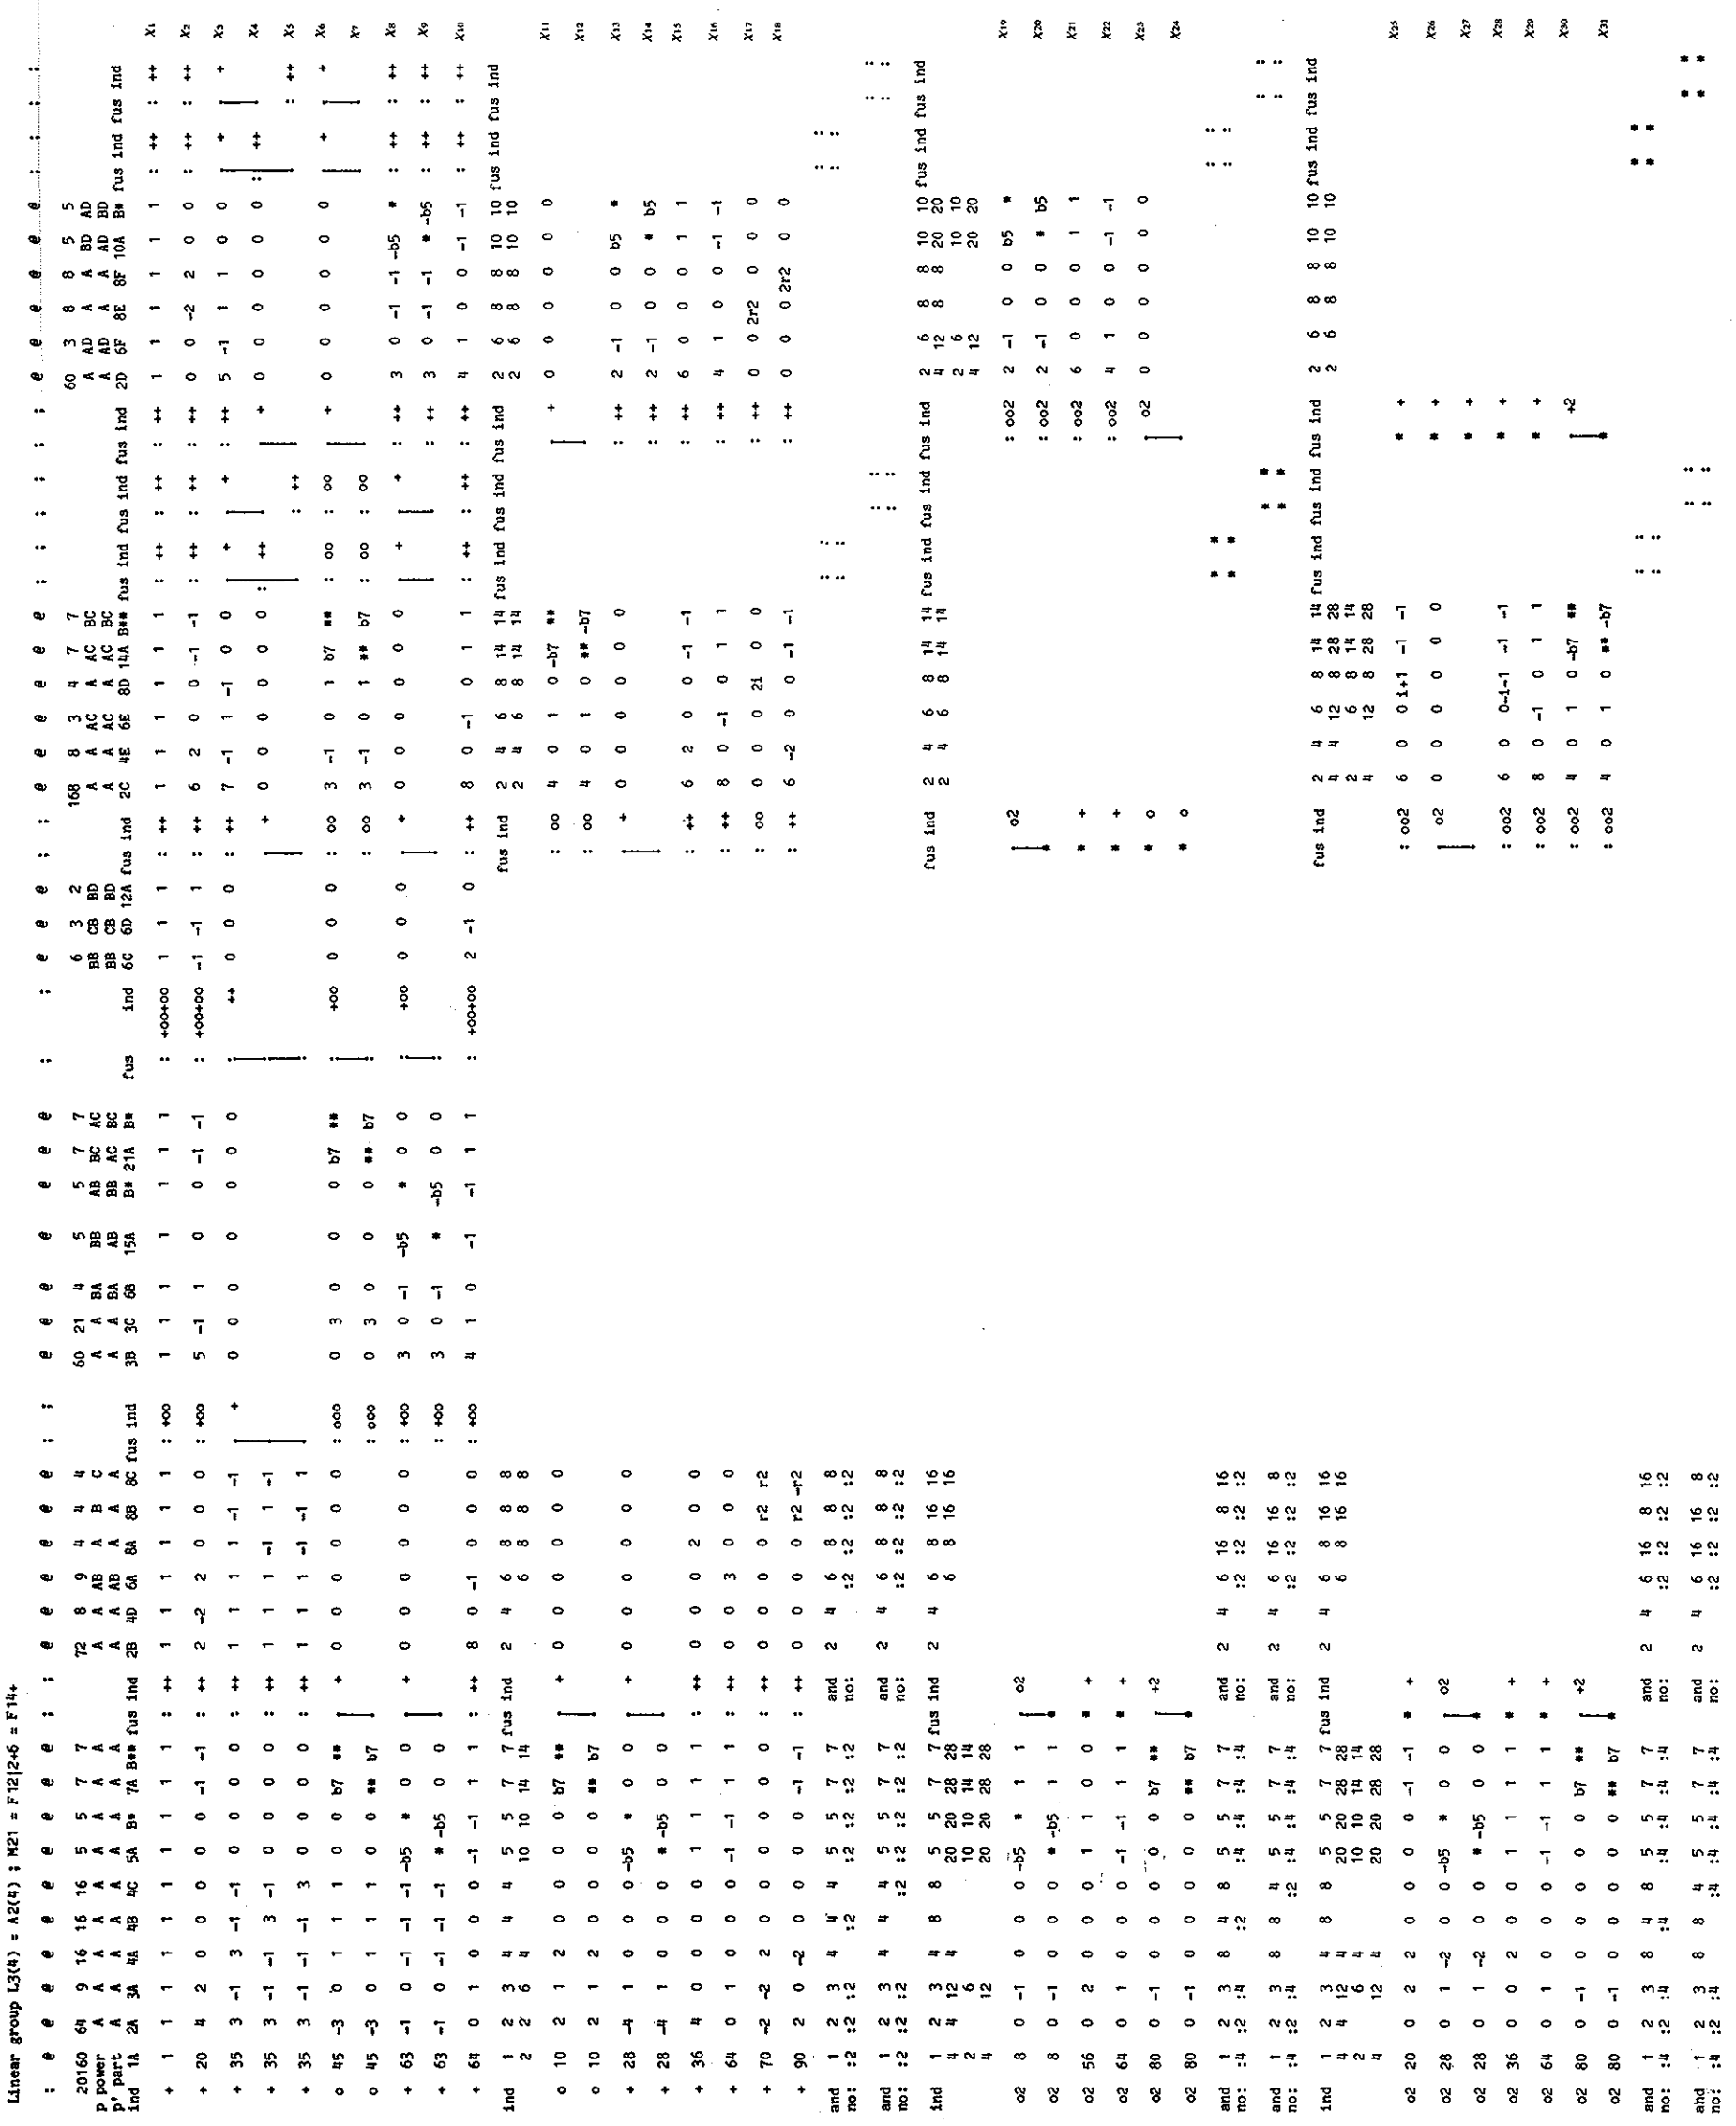
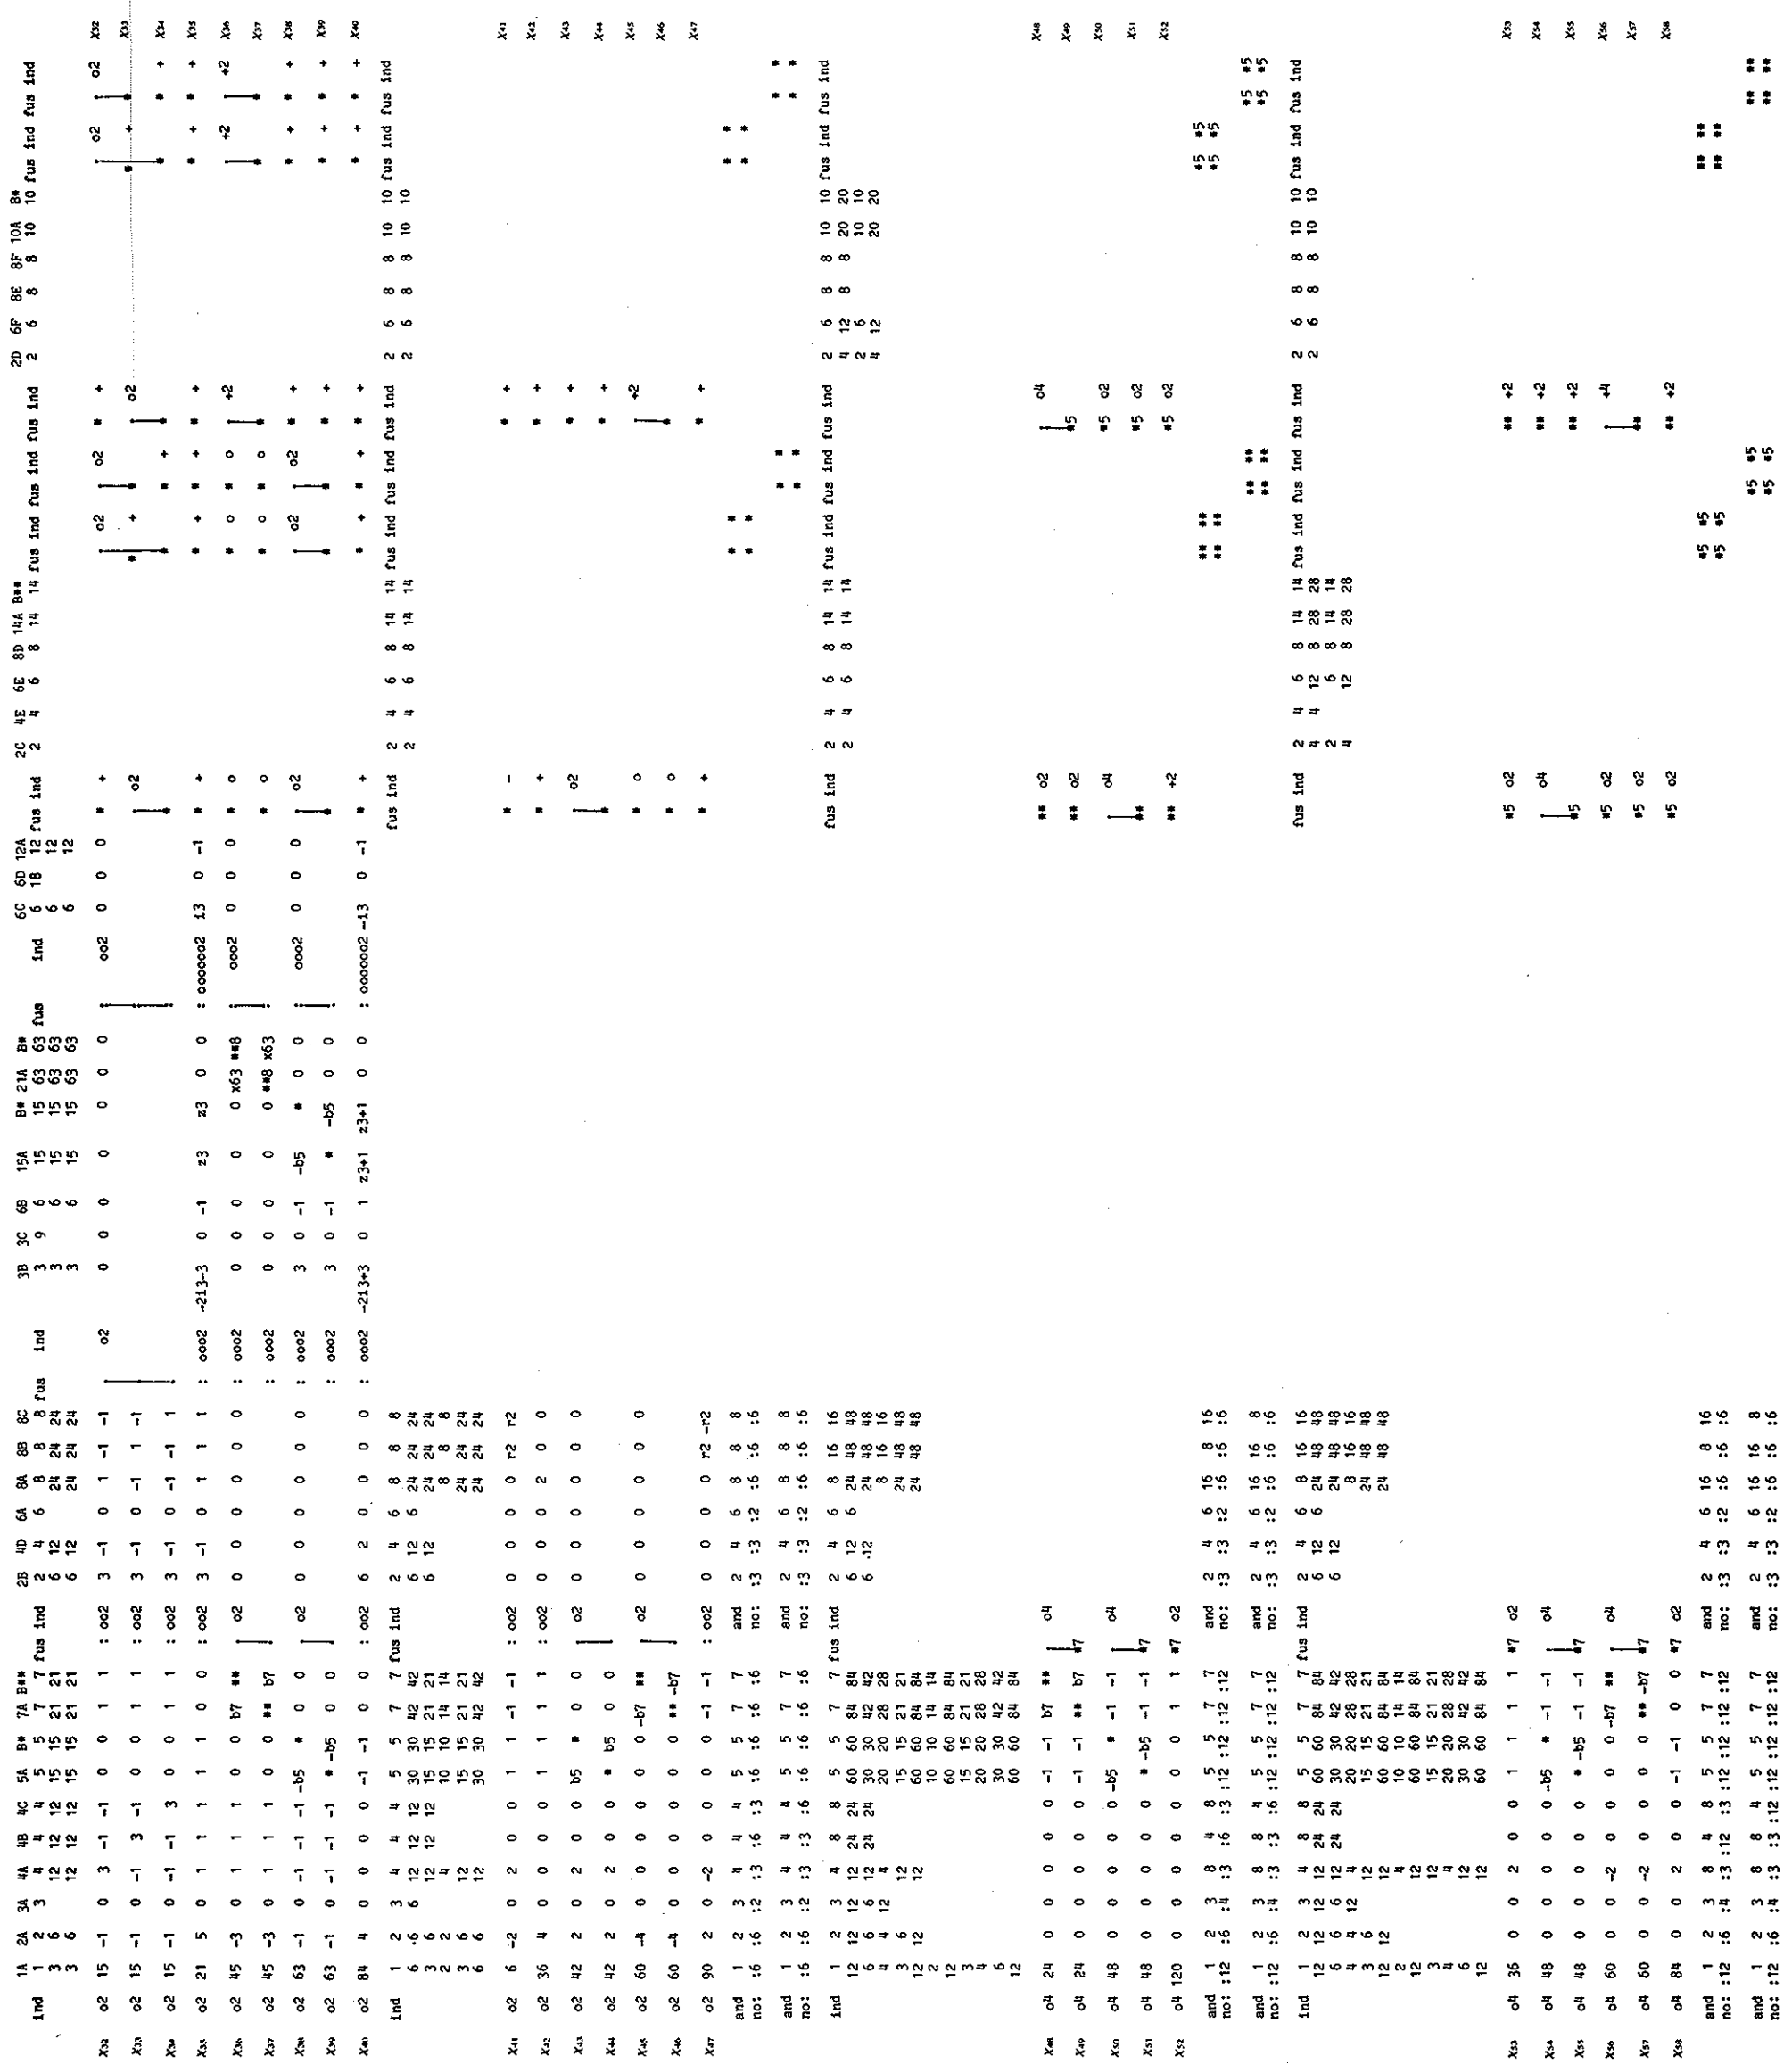
$L_3(4)$



$L_3(4)$



$U_4(2) \cong S_4(3)$

Unitary group $U_4(2) \cong {}^2A_3(2) \cong O_6^-(2)$; Symplectic group $S_4(3) \cong C_2(3) \cong O_5(3)$

Order = 25,920 = $2^6.3^4.5$ Mult = 2 Out = 2

Constructions

Unitary $GU_4(2) \cong 3 \times G$: all 4 x 4 matrices over $\mathbb{F}_4$ preserving a non-singular Hermitian form;

$PGU_4(2) \cong SU_4(2) \cong PSU_4(2) \cong G$

Orthogonal (2) $GO_6^-(2) \cong PGO_6^-(2) \cong SO_6^-(2) \cong PSO_6^-(2) \cong G.2$: all 6 x 6 matrices over $\mathbb{F}_2$ preserving a non-singular quadratic form of Witt defect 1, for example $x_1^2+x_1x_2+x_2^2+x_3x_4+x_5x_6$; $O_6^-(2) \cong G$

Orthogonal (3) $GO_5(3) \cong 2 \times G.2$: all 5 x 5 matrices over $\mathbb{F}_3$ preserving a non-singular quadratic form;

$PGO_5(3) \cong SO_5(3) \cong PSO_5(3) \cong G.2$; $O_5(3) \cong G$

G : the automorphism group of a generalized 4-gon of order (3,3) consisting of 40 vertices and 40 edges, each object being incident with 4 of the other type

Symplectic $Sp_4(3) \cong 2.G$: all 4 x 4 matrices over $\mathbb{F}_3$ preserving a non-singular symplectic form;

$PSp_4(3) \cong S_4(3) \cong G$;

Weyl G.2 : the Weyl group of E_6, generated by the 36 reflections in the minimal (root) vectors of the E_6 lattice; these may be taken as

$(0,0,0,0,0,0;1,-1)$ (1), $(1,-1,0,0,0,0;0,0)$ (15), $(\frac{1}{2},\frac{1}{2},\frac{1}{2},-\frac{1}{2},-\frac{1}{2},-\frac{1}{2};\frac{1}{2},-\frac{1}{2})$ (20) (first base)

or $(\pm1,\pm1,0,0,0;0,0,0)$ (20), $\pm(\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2};\frac{1}{2},\frac{1}{2},\frac{1}{2})$ (even sum) (16) (second base)

where the coordinates before the semicolon may be freely permuted.

The coordinates are obtained from the E_8 root lattice (see $O_8^+(2)$) by imposing the conditions

$x_1+x_2+x_3+x_4+x_5+x_6=0=x_7+x_8$ (first base) or $x_6=x_7=x_8$ (second base).

The Weyl group permutes the 27 vectors (which belong to one coset of the lattice in its dual E_6^*)

$a_i = (\frac{5}{6},-\frac{1}{6},-\frac{1}{6},-\frac{1}{6},-\frac{1}{6},-\frac{1}{6};\frac{1}{2},-\frac{1}{2})$ (6), $b_i = (\frac{5}{6},-\frac{1}{6},-\frac{1}{6},-\frac{1}{6},-\frac{1}{6},-\frac{1}{6};-\frac{1}{2},\frac{1}{2})$ (6), $c_{ij} = (-\frac{2}{3},-\frac{2}{3},\frac{1}{3},\frac{1}{3},\frac{1}{3};0,0)$ (15);

the full automorphism group of the lattice is 2 x G.2 and is obtained by adjoining negation.

Reducing modulo 2 shows the isomorphism with $O_6^-(2)$.

Biflection 2 x G : the group generated by the 45 complex reflections of order 2 in the vectors

$(\pm2,0,0,0,0)^C$ (5), $(0,\pm w,\pm\bar{w},\pm\bar{w},\pm w)^C$ (40), where w = z3.

Reducing mod θ = i3 shows the isomorphism with $O_5(3)$.

6 x G : the full automorphism group of the lattice these generate.

Triflection 3 x 2.G : the group generated by the 40 complex reflections of order 3 (triflections) in the ($\pm$w)vectors $(\theta;0,0,0)$ $(0;\theta,0,0)$ $(0;w^a,w^b,w^c)$ $(w^a;0,w^b,-w^c)$, where the last 3 coordinates may be cyclically permuted; the triflection in r takes v to $v - (1-w)(v.r)r/(r.r)$, where $x.y = \Sigma x_i\bar{y}_i$. Reducing mod 2 shows the isomorphism with $U_4(2)$; reducing mod θ shows the isomorphism with $S_4(3)$.

Schläfli G.2 : the group of the incidence-preserving permutations of the 27 lines on the general cubic surface in projective 3-space : a_i (6), b_i (6), c_{ij} (15) (i,j = 1, ... 6, i≠j). These lie in threes in 45 tritangent planes (a_i,b_j,c_{ij}) (30), (c_{ij},c_{kl},c_{mn}) (15) (i,j,k,l,m,n, distinct), and two lines intersect if and only if they lie in some tritangent plane. There are 36 "double sixes" such as $\{a_i|b_j\}$, in which each line of either "six" meets all but one line of the other "six".

Hesse G.2 : the stabilizer of a bitangent in Hesse's group (see $S_6(2)$) of symmetries of the 28 bitangents to the general quartic curve in the complex projective plane; the bitangents may be labelled with unordered pairs from {1,2,3,4,5,6,a,b} and the 27 bitangents other than ab then correspond naturally with Schläfli's 27 lines: ai $\longleftrightarrow a_i$, bj $\longleftrightarrow b_j$, ij $\longleftrightarrow c_{ij}$. Generating permutations may easily be obtained from Hesse's bifid maps (see $S_6(2)$) e.g. (a123|b456) and (ab12|3456)(a 1)(b 2). The 45 quartets {ab,bj,ji,ia} (30) and {ab,ij,kl,mn} (15) containing ab yield the 45 tritangent planes.

Presentations G.2 ≅  ; G x 2 ≅ <

Sz(8)

Suzuki group $Sz(8) \cong {}^2B_2(8)$

Order = 29,120 = $2^6.5.7.13$ Mult = 2^2 Out = 3

Constructions

Suzuki $Sz(8) \cong G$: the centralizer in $S_4(8)$ of an outer (graph) automorphism of order 2;

G : all 4 x 4 matrices over $\mathbf{F}_8$ preserving the set of vectors (t,x,y,z) for which $xy+(x^{s+2}+y^s+z)t=0$, where $s : x \to x^4$ is the automorphism of $\mathbf{F}_8$ with $s^2=2$; projectively this defines an oval of $8^2+1=65$ points on which G acts doubly transitively

Orthogonal 2.G has an 8-dimensional orthogonal representation over $\mathbf{F}_5$; it may be generated by the maps A and B which take $(x_\infty,x_0,\ldots,x_6)$ (subscripts mod 7) to $(x_4,-x_5,x_2,x_1,-x_6,x_\infty,x_0,x_3)$ and $(x_\infty,x_1,x_2,x_3,x_4,x_5,x_6,x_0)$, respectively, together with the map

$C : x_\infty \to 2x_\infty + x_0 + x_1 + x_2 + x_3 + x_4 + x_5 + x_6$

$x_t \to x_\infty - x_{-t} - x_{3-t} + x_{4-t} + 3x_{1-t} + 3x_{2-t} + 3x_{6-t}$

Complex G has a 14-dimensional complex representation which we write as a 7-dimensional representation over the quaternion algebra with units 1,j,k,l and complex coefficients a+bi; G is generated by

$A' : (q_0,\ldots q_6) \to (-iq_0,-ikq_1,-ilq_2,lq_3,-ijq_4,kq_5,jq_6)$

$B' : (q_0,\ldots q_6) \to (q_1,q_2,q_3,q_4,q_5,q_6,q_0)$

$C' : -4iq_n \to (i+j+k+l)q_{-n}+(i-l)q_{1-n}+(i-j)q_{2-n}+(l-k)q_{3-n}+(i-k)q_{4-n}+(k-j)q_{5-n}+(j-l)q_{6-n}$

this is connected with the fact that one of the involution centralizers in the Rudvalis group is $2^2 \times G$

Sporadic Mathieu group M_{12}

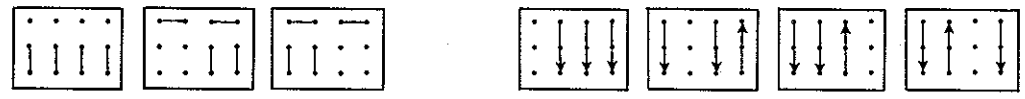
Order = 95,040 = $2^6.3^3.5.11$ Mult = 2 Out = 2

Constructions

Golay (3) code 2G : the automorphism group of the unique dimension 6, length 12 code over $\mathbb{F}_3$ of minimal weight 6 (the ternary Golay code) which is defined in several ways below.

The weight distributions of the code and the cocode (words modulo the code) are $0^1 6^{2x132} 9^{2x220} 12^{2x12}$ and $0^1 1^{2x12} 2^{2x132} 3^{2x220}$, respectively. The minimal weight representatives for the cocode are unique except that words of weight 3 are congruent in sets of 4 (whose supports are linked threes).

Steiner hexads G : the automorphism group of the Steiner system S(5,6,12) of 132 special hexads from a 12-set, such that each pentad is in just one special hexad. The hexads are the supports of the weight 6 words in the ternary Golay code. For a group element of shape $2^4 1^4$ or $3^3 1^3$, the fixed points together with any cycle form a hexad. Below we give, in the MINIMOG array, 3 involutions of a 4-group whose fixed tetrads (linked fours) are disjoint, and 4 elements of a 9-group any 2 of whose fixed triads (linked threes) form a hexad.



MINIMOG The MINIMOG constructs the code in such a way that both signed and unsigned hexads are easily recognized. Each word is written over $\mathbb{F}_3$ in three rows (row_o, row_+, row_-) of four digits each, and belongs to the code just if:

sum of each column = -(sum of row_o)

$row_+ - row_-$ is one of the tetracode words:

oooo o+++ o--- +o+- +-o+ ++-o -o-+ -+o- --+o (or in general $(a_\infty;a_0,a_1,a_2) = (s;a,a+s,a+2s)$.

For example we check -

+	+	+	+		column sums:	-	- - -
o	o	+	-	thus:	row_o sum: +	+	+ + +
+	+	o	-			o	o + -
						+	+ o -
					$row_+ - row_-$:	-	- + o

A hexad is in the Steiner system just if its column distribution is $3^2 0^2$, $3^1 1^3$, $2^3 0^1$, or $2^2 1^2$ and its "odd-men-out" form part of a tetracode word. For example

column distribution:	0 3 0 3	1 1 3 1	2 0 2 2	1 1 2 2
	* * / * * / * *	* * / * * / * *	* * * / * * / *	* * * / * * / *
odd-men-out:	? ? ? ?	+ o ? -	- ? - +	+ o + -

(if a point in a column is the only one in (resp. not in) the hexad, it is the odd man out for that column). We find the corresponding Golay code words using cols and tets:

col-col	col+tet	tet-tet	col+col-tet	a col	a tet
+ - / + - / + -	+ + / + - / + +	+ o + + / - - / -	- + + / - o + / + o	+ / + / +	+ / + / + / +

(Modulo the code we have (every col) ≡ -(every tet), where cols and tets are the obvious words of weight 3 and 4 corresponding to columns and tetracode words.)

Here is a dictionary between numberings of the 12-set and the MINIMOG array:

$-e_0$	e_3	e_∞	$-e_2$
$-e_5$	e_9	e_8	$-e_X$
$-e_4$	e_1	e_6	$-e_7$

d_4	d_6	d_8	d_{10}
$-d_5$	$-d_7$	$-d_9$	$-d_{11}$

lexicographic

Mathieu 24 G : the stabilizer in M_{24} of a weight 12 word (dodecad) in the binary Golay code. The hexads arise from octads of S(5,8,24) meeting the dodecad in 6 points. The outer automorphism interchanges the dodecad with its complement. The standard pair of dodecads is

Q = {0, quadratic residues modulo 23}, N = {∞, non-residues modulo 23}.

If we define n^+ = whichever of n, -n is in Q n^- = whichever of 8/n, -8/n is in N

we convert the modulo 23 numbering of the MOG into shuffle numberings for Q and N, thus:

0	∞	1	11	2	22
19	3	20	4	10	18
15	6	14	16	17	8
5	9	21	13	7	12

=

0^+	0^-	1^+	7^-	2^+	8^-
2^-	3^+	5^-	4^+	10^-	5^+
1^-	6^+	6^-	7^+	9^-	8^+
3^-	9^+	4^-	10^+	11^-	11^+

M_{12}

Modulo 11 The ternary Golay code is a quadratic residue code, modulo 11. Letting Q = {0, quadratic residues} = {0,1,3,4,5,9} and N = {∞,2,6,7,8,X=10 , the words $w_\infty = -\Sigma e_i$ and $w_i = \Sigma e_{q-i} - \Sigma e_{n-i}$ (over $\mathbf{F}_3$) and their negatives are called <u>total words</u>, and span the code. 2G is generated by the maps

$$e_i \to e_{A(i)} \qquad w_i \to w_{A^{-1}(i)}$$
$$e_i \to e_{B(i)} \qquad w_i \to w_{B(i)}$$
$$e_i \to \pm e_{C(i)} \qquad w_i \to \mp w_{C(i)} \qquad \text{(upper sign just on Q)}$$
$$e_i \to e_{D(i)} \qquad w_i \to w_{D(i)}$$

where A(i) = i+1, B(i) = 3i, C(i) = -1/i and D = (2X)(34)(59)(67). The group $\langle A,B,C\rangle \cong SL_2(11)$, so all automorphisms of the projective line are in G. The code is self-dual in the sense that $\Sigma c_i w_i = 0$ just when (c_i) is in the code. There is an outer automorphism E that interchanges the actions on e_i and w_i, and takes $A \to A^{-1}$, $B \to B$, $C \to C^{-1} = -C$, $D \to D$.

Loop G is generated by the multiplication maps $x \to x.a$ in the loop $\{E_\infty, E_0, \ldots E_X\}$ of order 12 defined by $E_t.E_t = E_\infty = 1$, $E_t.E_{t+q} = E_{t+2q}$, $E_t.E_{t+n} = E_{t-n}$ (q in Q, n in N). For each p in $L_2(11)$ there is a permutation p* such that $E_a.E_b = E_c \Rightarrow E_{p(a)}.E_{p(b)} = E_{p^*(c)}$ and G is generated by the p and p*. For the permutations given above, A* = A, B* = B, C* = D. These results extend (with some subtlety) to the loop of order 24 defined by $E_t.E_t = -E_\infty$, $E_t.E_{t+q} = -E_{t+2q}$, $E_t.E_{t+n} = E_{t-n}$, whose right multiplications generate 2G.

Orthogonal (2) G is the intersection of two subgroups A_{12} in $O^-_{10}(2)$, as follows:

the even subsets of {0,1,...11} modulo complementation form an orthogonal 10-space over $\mathbf{F}_2$ with quadratic form $q(X) = \frac{1}{2}|X|$. The reflections $x \to x - (x.r)r$ in the 11 duads r = {0,1},...{10,11} generate one subgroup S_{12}, while those in the 11 hexads with sum 21, namely

r = {1,2,3,4,5,6} {0,1,2,3,7,8} {0,1,2,4,5,9} {0,1,3,4,6,7} {0,1,2,3,5,10} {0,1,2,4,6,8}
{0,2,3,4,5,7} {0,1,2,3,6,9} {0,1,3,4,5,8} {0,1,2,5,6,7} {0,1,2,3,4,11}

generate the other. The outer automorphism of $O^-_{10}(2)$ interchanges the generators in the order given. The above hexads generate the Steiner system by reflection and complementation.

Shuffle G : the case n = 12 of the following construction:

If n|12 we define M_n to be the group of permutations of {0,1,...n-1} generated by the <u>reversal</u> and <u>Mongean shuffle</u> permutations: R : t → n-1-t S : t → min{2t,2n-1-2t}.

If mn = 12, the stabilizer in G of the canonical partition 0.../n.../2n.../... into m sets of n is a subgroup $M_m \times M_n$ acting on one of the standard arrays displayed:

0	1	2	3	4	5	6	7	8	9	10	11

0	1	2	3	4	5
6	7	8	9	10	11

0	1	2	3

4
5
6
7
8
9
10
11

The Steiner system is the same as that given under the "Orthogonal" construction above.

The outer automorphism : R → R, S → S^{-1} conjugates $M_m \times M_n$ to $M_n \times M_m$.

The shuffle numbering is related to the modulo 11 numbering as follows:

Shuffle:	0	1	2	3	4	5	6	7	8	9	10	11
Modulo 11:	∞	1	9	3	4	5	0	8	6	2	X	7
(mnemonic:	∞	1	-2	3	4	5	0	-3	6	-9	-12	-15)

G x 2 : the group of permutations on {0,1,2,...,23} generated by the <u>turnaround</u> permutations

$T_d : qd + r \to qd + d - 1 - r \quad (0 \le r < d)$ for each divisor d of 24

There is an outer automorphism taking T_d to $T_{24/d}.(T_{24})^{d+24/d}$

Hadamard 2G : the automorphism group of any 12 x 12 Hadamard matrix (that is, a matrix with orthogonal rows and entries ±1); the outer automorphism interchanges rows with columns. Particular definitions of Hadamard matrices are

(modulo 11) : $a_{ij} = \pm 1$ according as i is in Q or N

(shuffle) : $a_{ij} = (-1)^{[(ij+i+j-1)/13]}$

An automorphism is a monomial permutation of rows that has the same effect as some monomial permutation of columns.

Lexicographic The code is generated by 6 words, written $(d_0,\ldots d_{11})$, each the lexicographically earliest word that differs in at least 6 places from all linear combinations of its predecessors:

000000111111 000011001122 000101010212 001001012021 010001021201 100001022110

Presentations $G \cong G^{3,5,5,5,5,5,5} \cong \langle A,B,C,D \mid A^{11}=B^5=C^2=D^2=(BC)^2=(BD)^2=(AC)^3=(AD)^3=(DCB)^2=1, A^B=A^3\rangle$

$\cong \langle A,C,D \mid A^{11}=C^2=D^2=(AC)^3=(AD)^3=(CD)^{10}=1, A^2(CD)^2A=(CD)^2\rangle$

$U_3(5)$

Unitary group $U_3(5) \cong {}^2A_2(5)$

Order = 126,000 = $2^4.3^2.5^3.7$ Mult = 3 Out = S_3

Constructions

Unitary $2 \times 3.G.3 \cong GU_3(5)$: all 3×3 matrices over $\mathbb{F}_{25}$ preserving a non-singular Hermitian form;

$PGU_3(5) \cong G.3$; $SU_3(5) \cong 3.G$; $PSU_3(5) \cong G$;

Graph G.2 : the automorphism group of the Hoffman-Singleton graph, a rank 3 graph on 50 vertices, in which the vertex stabilizer is A_7, and the suborbits are 1, 7, 42. The vertices may be labelled by ∞ (1), 0,1,...6 (7), and the 42 totals (see A_6) on 6-element subsets of {0,1,...6}. The vertex i joins ∞ and the totals on the set disjoint from {i}; two totals are joined if A_7 contains an element of order 5 fixing them both. There are two systems of 50 sets (co-cliques) of 15 points no two of which are joined.

Leech $2 \times G.S_3$: the set stabilizer in $2Co_1$ of an S-lattice of type $3^{1+3}2^3$ (see Co_1); the pointwise stabilizer is G; hence G appears in Co_2, Co_3, HiS, and McL, which stabilize various sublattices of this S-lattice.

Remark : G.2 is a maximal subgroup of the Rudvalis group.

J_1

Sporadic Janko group J_1

Order = 175,560 = $2^3.3.5.7.11.19$ Mult = 1 Out = 1

Constructions

Janko G is a subgroup of $G_2(11)$: in the 7-space of pure imaginary Cayley numbers over F_{11}, spanned by i_t (subscripts mod 7), G may be generated by the elements

$P : i_t \to i_{t+1}$; $Q : i_t \to i_{2t}$; $R : i_t \to \pm i_t$ (- for t=0,3,5,6) ;

$S : i_t \to -2i_{-t} + (i_{1-t}+i_{2-t}+i_{4-t}) + 3(i_{6-t}+i_{5-t}+i_{3-t})$.

In the corresponding projective 6-space there is an orbit of 1596 (isotropic) "Whitelaw points" each lying in two out of 266 normal sextic curves of 12 such points.

Graph G : the automorphism group of an 11-valent graph on 266 points in which the point stabilizer is $L_2(11)$ and the suborbits have size 1 (distance 0), 11 (distance 1), 110 (distance 2), 132 (distance 3) and 12 (distance 4, or opposite). There are 11 involutions indicated by superscripts i,j from {0,1,2,...,8,9,X}, the involution 0 being DCDCD below. In these terms the 266 points can be written P (1), P^i (11), $P^{i,j}$ (110), Q_x (12), and $Q_x{}^i$ (132), for x = ∞,0,1,...,9,X; P is joined to P^i and opposite to Q_x. The group is generated by the elements

A : t → t+1, B : t → 3t, on i,j,x

C : (2X)(34)(59)(67) on i,j, and (∞0)(1X)(25)(37)(48)(69) on x

$D : (P^{t,t+q} , Q_{q-t}{}^{5q-t}) (P^{t,t-q} , P^{-t,-t-q}) (Q_t{}^{t+q} , P^{3q-t,6q-t}) (Q_t{}^{t-q} , Q_{-t-2q}{}^{-t-3q})$

$(P , Q_\infty) (P^t , Q_{-t}{}^{-t}) (Q_t , Q_\infty{}^{-t})$, (t = 0,1,...,9,X, q = 1,3,4,5,9)

Orthogonal (2) In the 20-space over F_2 of vectors $v = \Sigma x_t e_t + \Sigma y_t f_t$ (subscripts mod 11) with $\Sigma x_t = \Sigma y_t = 0$ and invariant quadratic form $q(v) = \Sigma x_t y_t$, the above generators act as follows:

$A : e_t \to e_{t+1}$ $f_t \to f_{t+1}$

$B : e_t \to e_{3t}$ $f_t \to f_{3t}$

$C : e_0 \to e_0$ $f_0 \to f_0 + e_0'$, where $e_t' = \Sigma e_i$ $(i \neq t)$

$e_t \to e_{1/t}$ $f_t \to f_{1/t} + e_0 + e_{3/t} + e_{4/t} + e_{8/t}$ (t = 1,3,4,5,9)

$e_t \to e_{9/t}$ $f_t \to f_{9/t} + e_0 + e_{3/t} + e_{4/t} + e_{8/t} + e_{1/t} + e_{5/t}$ (t = 2,6,7,8,10)

$D : e_t \to f_{-t}$ $f_t \to e_{-t}$

Presentation $G = \langle \underline{a \quad b\ 5\ c \quad d\ 5\ e} \mid (abc)^5=1, (cde)^5=a \rangle$

Remark : G is the centralizer in the O'Nan group of an outer automorphism of order 2.

Alternating group A_9

Order = 181,440 = $2^6.3^4.5.7$ Mult = 2 Out = 2

Constructions

Alternating $S_9 \cong G.2$: all permutations of 9 letters;

$A_9 \cong G$: all even permutations; 2.G and 2.G.2 : the Schur double covers

Orthogonal 2G has an 8-dimensional real orthogonal representation, which may be generated (with subscripts modulo 7) by

$A : e_t \to e_{t+1}$, $B : e_t \to e_{2t}$, $C : e_t \to e_{-1/t}$, $D : e_t \to \pm e_t$ (− for 0,3,5,6) and

$E : 4e_\infty \to -2e_\infty-3e_0-e_3-e_5-e_6$ $\quad 4e_0 \to -2e_0+3e_\infty+e_1+e_2+e_4$

$4e_n \to -2e_n-3e_{3n}+e_\infty-e_{5n}+e_{6n}$ (n = 3,5,6) $\quad 4e_q \to -2e_q+3e_{5q}-e_0-e_{6q}+e_{3q}$ (q = 1,2,4)

which permute $\{\infty,0,\ldots 6,Z\}$ as (0123456), (124)(365), (∞0)(16)(23)(45), (∞0)(23)(15)(46), and (0∞Z) respectively

Presentations $G \cong \langle x_1,\ldots x_7 | x_i^3=(x_ix_j)^2=1\rangle$; G.2 ≅

Sporadic Mathieu group M_{22}

Order = 443,520 = $2^7.3^2.5.7.11$ Mult = 12 Out = 2

Constructions

Mathieu For almost all purposes, M_{22} is best studied as a subgroup of M_{24} (q.v.). Thus $M_{22}.2 \cong G.2$ is the set stabilizer of a duad in M_{24}, and $M_{22} \cong G$ is the pointwise stabilizer.

$M_{22}.2 \cong G.2$: the automorphism group of the Steiner system S(3,6,22), whose 77 hexads are derived from the octads of S(5,8,24) containing the fixed duad.

Graph G.2 : the automorphism group of a rank 3 graph on 77 points, with suborbits 1, 16, 60, and point stabilizer $2^4{:}S_6$. (Every hexad of S(3,6,22) is disjoint from 16 others and meets the remaining 60 in 2 points each.)

Lattice $2M_{22}.2 \cong 2.G.2$: the automorphism group of a 10-dimensional lattice with coordinates (in $\mathbf{Z}[b7]$) indexed by the triples of 6 points, modulo complementation. The lattice is defined by requiring all coordinates x_{abc} to be congruent modulo b7 and their sum to be divisible by 2b7**, while their sums over sets of the form S(ab.cd.ef) = {ace,acf,ade,adf} and S(ab) = {abc,abd,abe,abf} must be divisible by 2 and $(b7)^2$ respectively. There is a monomial group $2^5{:}S_6$ generated by permutations of {a,b,c,d,e,f} and sign changes on the sets S(ab.cd.ef). With the natural norm $\frac{1}{4}\Sigma|x_{abc}|^2$ the vectors of norms 4 and 5 fall into four orbits 4X, 4Y, 5X, 5Y. The vectors of 4X are the images under the monomial group of

(4,0,0,0,0,0,0,0,0,0)

(i7,1,1,1,1,1,1,1,1,1)

(1,1,1,1,b7**,b7**,b7**,b7**,b7**,b7**) (1 on S(ab))

(b7,b7,b7,b7,0,0,0,0,2,-2) (b7 on S(ab), 0 on S(ab.cd.ef))

and fall into 77 congruence bases modulo b7**.

Unitary In a 6-dimensional vector space of vectors (ab cd ef) over $\mathbf{F}_4$ with unitary norm $\bar{a}b+a\bar{b}+\bar{c}d+c\bar{d}+\bar{e}f+e\bar{f}$, the group $3M_{22} \cong 3G$ is the automorphism group of a configuration of 22 isotropic vector 3-spaces. Each non-zero isotropic vector appears in just two of these spaces. The coordinates (ab cd ef) of a typical vector in each of the 22 3-spaces are given in the MOG array below, where x,y,z are independent elements of $\mathbf{F}_4 = \{0,1,w,\bar{w}\}$, X = y+z, Y = x+z, Z = x+y, S = x+y+z, and A' = wA, B" = $\bar{w}$B :

$J_2 = HJ = F_{5-}$

Sporadic Hall-Janko group J_2

Order = 604,800 = $2^7.3^3.5^2.7$ Mult = 2 Out = 2

Constructions

Graph $J_2.2 \cong G.2$: the automorphism group of a rank 3 graph on 100 points, with suborbits 1, 36, 63, and point stabilizer $U_3(3).2 \cong G_2(2)$. This graph is one of a series continuing through $G_2(4)$ and Suz.

Quaternionic $2J_2 \cong 2.G$: a group generated by 315 quaternionic reflections. There is a diagonal subgroup 2^{3+4} of right multiplications diag(g_1,g_2,g_3) (g_t in {±1,±i,±j,±k}) with $g_1g_2g_3 = \pm 1$, and the reflecting vectors (roots) are the images under this of $(2,0,0)^S$ (3), $(0,h,h)^S$ (24), $(\bar{h},1,1)^S$ (96), and $(1,wc,b\bar{w})^S$ (192) (where $w=\frac{1}{2}(-1+i+j+k)=z3$, b=b5, c=b5*, h=z3-b5). The ring of left scalar multiplications is the icosian ring, which contains $2A_5$ as a group of units (see A_5). The quaternionic reflections $x \longrightarrow x - 2\langle x,m\rangle m/\langle m,m\rangle$ preserve the quaternionic inner product $\langle x,y\rangle = \Sigma x_t\bar{y}_t$. The Euclidean norm defined by N(x) = a+b when $\langle x,x\rangle$ = a+b√5 (a,b rational), converts the lattice generated by the above vectors into the Leech lattice. Some of the subgroups are definable over proper subrings, often realizable by complex numbers, for example $\langle hj\rangle \cong \mathbb{Z}[b7]$.

Presentations $G \cong \langle a,b,u,v \mid u=ab, v=ab^{-1}, a^2=b^3=u^{15}=(u^4v^2u^3v^3)^2=(u^3v(u^2v^2)^2)^2=1\rangle$;

$2\cdot(S_3 \times G) \cong \langle$ a 5 b c 8 d e $\mid a = (cd)^4 \rangle$: adjoin $(bcde)^{10} = 1$ for 2 x G, $(abcdecbdc)^7 = 1$ for G.

$G.2 \cong \langle$ a b c 8 d e f $\mid a=(cd)^4, (bcde)^8=1 \rangle$

Constructions

Symplectic $Sp_4(4) \cong PSp_4(4) \cong S_4(4) \cong G$: all 4 x 4 matrices over $\mathbb{F}_4$ preserving a non-singular symplectic form;

$\Gamma S_4(4) \cong G.2$;

$C_2(4).2 \cong G.2$: the automorphism group of a generalised 4-gon of order (4,4), consisting of 85 vertices and 85 edges, each object being incident with 5 of the other type

G.4 is obtained by adjoining the duality (graph) automorphism, interchanging vertices and edges

Orthogonal $GO_5(4) \cong PGO_5(4) \cong SO_5(4) \cong PSO_5(4) \cong G$: all 5 x 5 matrices over $\mathbb{F}_4$ preserving a non-singular quadratic form;

$O_5(4) \cong G$;

Presentation $G \times 2 \cong \langle \overset{a}{\bullet}\!\!-\!\!\overset{5}{\bullet}\!\!-\!\!\overset{b}{\bullet}\!\!-\!\!\overset{5}{\bullet}\!\!-\!\!\overset{c}{\bullet}\!\!-\!\!\overset{d}{\bullet}\!\!-\!\!\overset{e}{\bullet} \mid (abc)^4=1 \rangle$

Remark : G.2 is a maximal subgroup of the Held group.

$S_6(2)$

Symplectic group $S_6(2) \cong C_3(2)$; Orthogonal group $O_7(2) \cong B_3(2)$

Order = 1,451,520 = $2^9.3^4.5.7$ Mult = 2 Out = 1

Constructions

Symplectic $Sp_6(2) \cong PSp_6(2) \cong S_6(2) \cong G$: all 6 x 6 matrices over $\mathbf{F}_2$ preserving a non-singular symplectic form

Orthogonal $GO_7(2) \cong PGO_7(2) \cong SO_7(2) \cong PSO_7(2) \cong O_7(2) \cong G$: all 7 x 7 matrices over $\mathbf{F}_2$ preserving a non-singular quadratic form;

Weyl 2 x G : the Weyl group of E_7; the vectors may be taken as the vectors of the E_8 root lattice (see $O_8^+(2)$) with $x_1+\ldots+x_8 = 0$ (first base) or $x_7 = x_8$ (second base); the minimal (root) vectors are (in the first base) $(1,-1,0,0,0,0,0,0)^S$ (28) and $(\frac{1}{2},\frac{1}{2},\frac{1}{2},\frac{1}{2},-\frac{1}{2},-\frac{1}{2},-\frac{1}{2},-\frac{1}{2})^S$ (35), reflections in which correspond respectively to transpositions (ab) in S_8, and Hesse's bifid maps (abcd|efgh) (see below); the minimal vectors of the dual lattice E_7^* are $\pm(\frac{3}{4},\frac{3}{4},-\frac{1}{4},-\frac{1}{4},-\frac{1}{4},-\frac{1}{4},-\frac{1}{4},-\frac{1}{4})^S$ and correspond to the 28 bitangents ab.
Reducing mod 2 shows the isomorphism with $O_7(2)$.

Hesse G : there are 28 bitangents to the general plane quartic curve, which in Cayley's notation are labelled by the 28 unordered pairs ab, ... gh of 8 objects. The group is generated by Hesse's bifid maps such as (abcd|efgh) = (ab,cd)(ac,bd)(ad,bc)(ef,gh)(eg,fh)(eh,fg). The relations $(abcd|efgh)^2=1$, (abcd|efgh)(abce|dfgh)=(abce|dfgh)(de), (abcd|efgh)(abef|cdgh)=(abgh|cdef)(ab)(cd)(ef)(gh) show that the subgroup S_8 of permutations of {1,2,...8} has index 36, and coset representatives the identity together with the 35 bifid maps. These 35 maps together with the 28 transpositions of S_8 form the conjugacy class of "Steiner transpositions"; the group preserves the 315 quartets such as {ab,cd,ef,gh} (105), {ab,bc,cd,da} (210), whose 8 points of contact lie on a conic

$L_3(7)$

Linear group $L_3(7) \cong A_2(7)$

Order = 1,876,896 = $2^5.3^2.7^3.19$ Mult = 3 Out = S_3

Constructions

Linear $GL_3(7) \cong 2 \times 3.G.3$: all non-singular 3×3 matrices over $\mathbb{F}_7$;

$PGL_3(7) \cong G.3$; $SL_3(7) \cong 3.G$; $PSL_3(7) \cong G$

Remark : The O'Nan group contains two classes of maximal subgroups isomorphic to $L_3(7):2$.

$U_4(3)$

Unitary group $U_4(3) \cong {}^2A_3(3) \cong O_6^-(3)$

Order = 3,265,920 = $2^7.3^6.5.7$ Mult = $3^2 \times 4$ Out = D_8

Constructions

Unitary (3) $GU_4(3) \cong 4.G.4$: all 4 x 4 matrices over $\mathbf{F}_9$ preserving a non-singular Hermitian form;

$PGU_4(3) \cong G.4$; $SU_4(3) \cong 4.G$; $PSU_4(3) \cong G$

Orthogonal (3) $GO_6^-(3) \cong 2.G.(2^2)_{122}$: all 6 x 6 matrices over $\mathbf{F}_3$ preserving a non-singular quadratic form of Witt defect 1, for example $x_1^2 + x_2^2 + x_3^2 + x_4^2 + x_5^2 + x_6^2$; $PGO_6^-(3) \cong G.(2^2)_{122}$; $SO_6^-(3) \cong SO_6^-(3) \cong 2.G.2_1$; $PSO_6^-(3) \cong G.2_1$; $O_6^-(3) \cong G$

Unitary (2) $3.G.2_2$ has a 6-dimensional unitary representation over $\mathbf{F}_4$ (see $U_6(2)$). This can be obtained from the representation of $6_1.G.2_2$ as a complex reflection group (see below).

Leech $U_4(3).D_8 \cong G.D_8$: the set stabilizer in Co_1 of an S-lattice of type $2^{1+4}3^2$; the pointwise stabilizer is G (see Co_1); hence G is the point stabilizer in the 275-point representation of the McLaughlin group.

Complex Leech $(2x3^2).G.D_8$: the normalizer in $2Co_1$ of an elementary Abelian 3^2-group; $(2x3^2).G$: the centralizer, i.e. the centralizer in 6Suz of an element of order 3. When the Leech lattice vectors are written as quaternionic vectors $(q_1,\ldots,q_6)$ the 3^2-group is generated by left and right multiplication by $w = \frac{1}{2}(-1+i+j+k)$

Reflection $6_1.G.2_2$: the automorphism group of the 6-dimensional lattice over $\mathbf{Z}[w]$ (where w = z3) whose typical vector is $v_1+\theta v_2$ (with θ = i3, v_1 in the E_6 root lattice, v_2 in its dual). The group is generated by the 126 reflections in the 6 x 126 minimal vectors, which are listed (modulo scalars) in four bases below. Each base renders a different maximal subgroup monomial. The standard norm in the n-base is $\frac{1}{n}\Sigma|x_i|^2$, and modulo scalars there are 126, 672, 3402 vectors of norm 2, 3, 4 respectively. Read modulo θ these numbers become 126, 112, 126 and we obtain the "Orthogonal (3)" construction. Read modulo 2 they become 126, 672, 567 and we have the "Unitary (2)" construction.

In the 2-base the vectors are just those whose coordinates reduce modulo 2 to give a hexacode word (see A_6). The monomial subgroup (of 6.G.2) is $(2^6 \times 3)A_6$, and the minimal vectors are the images under this group of $(2,0,0,0,0,0)$ (6) and $(0,1,0,1,w,\bar{w})$ (120).

In the 3-base the monomial subgroup is $(2 \times 3^5)S_6$ and the minimal vectors are of form $(w^a\theta,-w^b\theta,0,0,0,0)^S$ (45) and $(w^a,w^b,w^c,w^d,w^e,w^f)^S$ $(a+b+c+d+e+f \equiv 0 \bmod 3)$ (81).

In the 4-base the monomial subgroup is $(3 \times 2^5)S_6$ and the minimal vectors are $(\pm2,\pm2,0,0,0,0)^S$ (30) and $(\pm\theta,\pm1,\pm1,\pm1,\pm1,\pm1)^S$ (even signs) (96).

In the 7-base the monomial group is $6 \times S_7$ and the minimal vectors are $(2+3w,-2-3w,0,0,0,0,0)^S$ (21) and $(2w,-2-w,-2-w,1,1,1,1)^S$ (105).

(Another type of 7-base is obtained by taking the complex conjugates of these numbers.)

Presentations $6_1.G.2_2 \cong$ 
$\langle\ |\ (cdcf)^3=1\ \rangle$;

$3^2.G.(2^2)_{133} \cong$ 
$\langle\ |\ f=(ab)^4=(de)^4,\ 1=(bcdf)^5\ \rangle$; normal 3^2 is generated by $(cbaba)^5$ and $(cdede)^5$

See also page 232.

$G_2(3)$

Chevalley group $G_2(3)$

Order = 4,245,696 = $2^6.3^6.7.13$ Mult = 3 Out = 2

Constructions

Chevalley G : the adjoint Chevalley group of type G_2 over F_3; G.2 is obtained by adjoining the graph automorphism;

G : the automorphism group of a generalized hexagon of order (3,3) consisting of 364 vertices and 364 edges, each object being incident with 4 of the other type; G.2 is obtained by adjoining an automorphism interchanging vertices and edges

Cayley G : the automorphism group of the mod 3 Cayley algebra of vectors $\Sigma a_n i_n$, with a_n in F_3 (subscripts mod 7), where n runs over $\{\infty,0,1,2,3,4,5,6\}$ and $i_\infty=1$, $i_{n+1}=i$, $i_{n+2}=j$, $i_{n+4}=k$ form a quaternion subalgebra

14-dimensional G.2 acts on a 14-space with base $\{e_\infty,e_0,\ldots e_{12}\}$ and is generated by

$A : e_t \to e_{t+1}$, $B : e_t \to e_{3t}$, $C : (e_2\ e_{12}\ -e_8)\ (e_6\ e_{10}\ -e_{11})\ (e_5\ e_4\ -e_7)$

$D : \sqrt{-3}.e_\infty \to 3e_\infty + \sqrt{3}.\Sigma e_i\ (i \neq \infty)$

$\sqrt{-3}.e_i \to \sqrt{3}e_\infty -3(e_{5i}+e_{5i+2}+e_{5i+5}+e_{5i+4}) +(e_{5i+1}+e_{5i+3}+e_{5i+4}+e_{5i+7}+e_{5i+8}+e_{5i+9}+e_{5i+10}+e_{5i+11}+e_{5i+12})$

$D^2: e_\infty \to -e_\infty$, $e_i \to -e_{2-i}-e_{4-i}-e_{5-i}-e_{6-i}+e_{7-i}+e_{8-i}-e_{10-i}+e_{11-i}-e_{12-i}$

The subgroup $G_2(3) = \langle A,B,C,C^D\rangle$ is represented by real matrices. There are 2 x 378 images under $G_2(3)$ of each of the vectors $(\sqrt{3}|0^{13})$ and $(3|\sqrt{3}^{13})$. These vectors are fixed by the respective subgroups $\langle A,B,C\rangle$ and $\langle A,B,C^D\rangle$ of type $L_3(3)$, and negated by D^2. The two orbits are interchanged by outer elements of $G_2(3).2$.

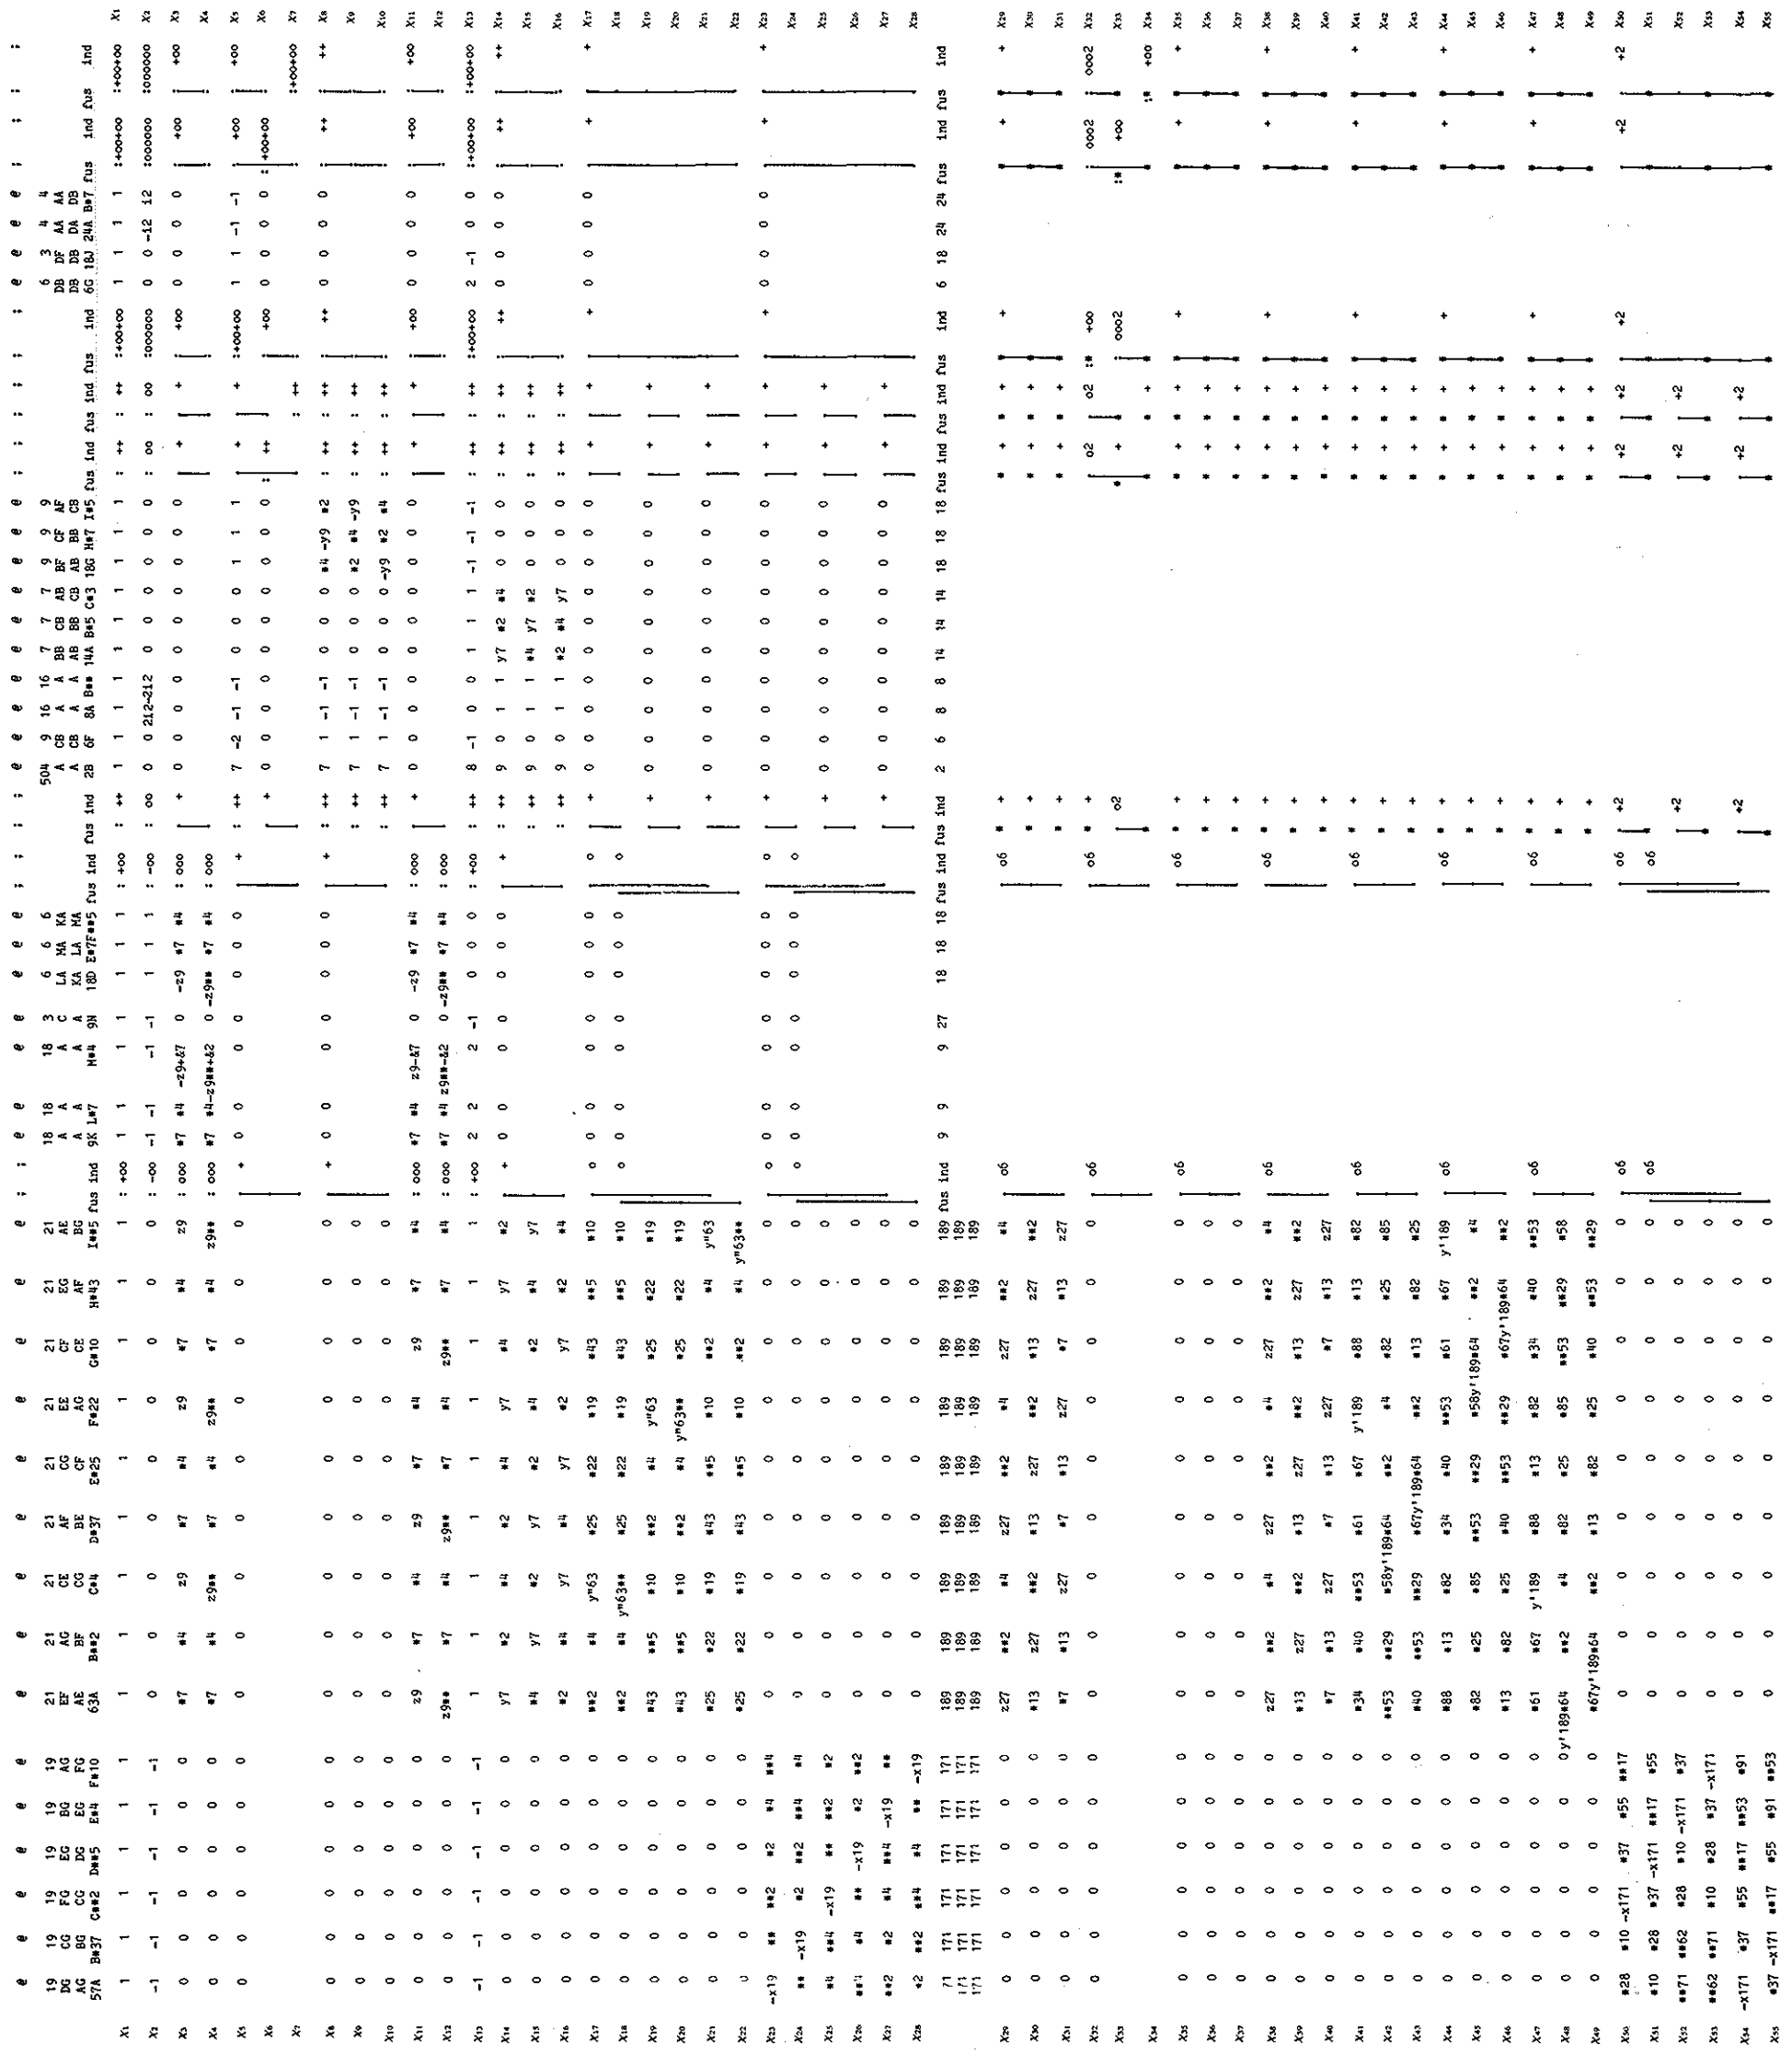
$U_3(8)$

$U_3(8)$



$U_3(8)$ and $U_3(7)$

Unitary group $U_3(8) \cong {}^2A_2(8)$

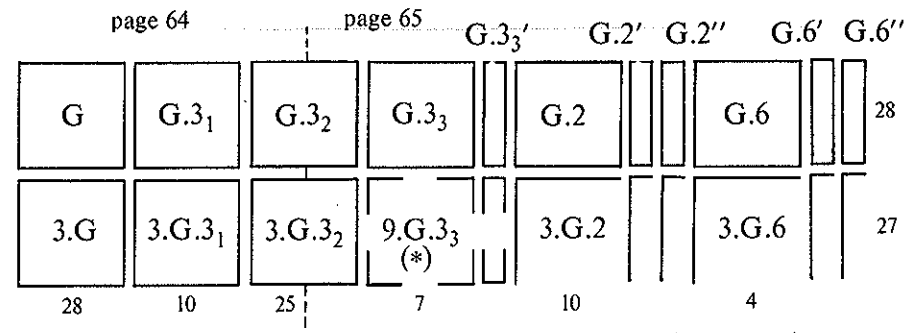
Order = 5,515,776 = $2^9.3^4.7.19$ Mult = 3 Out = $3 \times S_3$

Constructions

Unitary $GU_3(8) \cong 3.(3 \times G).3_2$: all 3×3 matrices over $\mathbf{F}_{64}$ preserving a non-singular Hermitian form;

$PGU_3(8) \cong G.3_2$; $SU_3(8) \cong 3.G$; $PSU_3(8) \cong G$

Remark : $G.3_1$ is a maximal subgroup of the Harada-Norton group, while G.6 is a maximal subgroup of the Thompson group.



(*) There is no group $3.G.3_3$ or $3.G.3_3'$. See the Introduction: 'Isoclinism'.

$L_5(2)$

Linear group $L_5(2) \cong A_4(2)$

Order = 9,999,360 = $2^{10}.3^2.5.7.31$ Mult = 1 Out = 2

Constructions

Linear $GL_5(2) \cong PGL_5(2) \cong SL_5(2) \cong PSL_5(2) \cong G$: all 5 x 5 non-singular matrices over F_2.

Presentations $2^5{:}G \cong \langle$  $\mid (bcf)^3=(abcd)^6=1 \rangle$; adjoin $(fbacde)^5=1$ for G

Remark : There is a non-split extension $2^{5\cdot}L_5(2)$ (the Dempwolff group), which is a maximal subgroup of the Thompson group.

Sporadic Mathieu group M_{23}

Order = 10,200,960 = $2^7.3^2.5.7.11.23$ Mult = 1 Out = 1

Constructions

Mathieu For almost all purposes, M_{23} is best studied as the point stabilizer in M_{24} (q.v.). Thus, G is the automorphism group of the Steiner system S(4,7,23), whose 253 heptads arise from the octads of S(5,8,24) containing the fixed point.

Golay G : the automorphism group of the (unextended) binary Golay code of dimension 12, length 23, and minimal weight 7, or of its subcode of even weight words. The weight distribution of the code is $0^1 7^{253} 8^{506} 11^{1288} 12^{1288} 15^{506} 16^{253} 23^1$, and that of the cocode (words modulo the code) $0^1 1^{23} 2^{253} 3^{1771}$. The minimal representatives in the cocode are unique (i.e. the code is a perfect 3-error correcting code).

Presentation $G \cong \langle$  $\mid a=(cf)^2, b=(ef)^3, 1=(eab)^3=(bce)^5=(aecd)^4=(bcef)^4 \rangle$

$U_5(2)$

Unitary group $U_5(2) \cong {}^2A_4(2)$

Order = 13,685,760 = $2^{10}.3^5.5.11$ Mult = 1 Out = 2

Constructions

Unitary $GU_5(2) \cong 3 \times G$: all 5 x 5 matrices over F_4 preserving a non-singular Hermitian form;

$PGU_5(2) \cong SU_5(2) \cong PSU_5(2) \cong G$

Quaternionic $G \times 2$: the group generated by the 165 quaternionic reflections $x \longrightarrow x - 2\langle x,m\rangle m/\langle m,m\rangle$ in the vectors $(2,0,0,0,0)^C$ (5), $(0,w,\bar{w},\bar{w},w)^C$ (160) and their images under the diagonal group $2 \times 2^{4+4} = \{\mathrm{diag}(\pm 1,\pm j,\pm k,\pm k,\pm j)^C\}$ of right multiplications, where $w = \frac{1}{2}(-1+i+j+k)$, and $\langle x,y\rangle = \Sigma x_t \overline{y_t}$. The vectors whose coordinates are in $\mathbf{Z}[w]$ form a complex lattice whose automorphism group is $6 \times U_4(2)$ (see $U_4(2)$, "biflection").

Reducing modulo 1+i shows the isomorphism with $U_5(2)$.

Complex Leech G : the stabilizer of a minimal vector in the complex Leech lattice (see Suz).

Tits group = derived Ree group $R(2)' \cong {}^2F_4(2)'$

Order = 17,971,200 = $2^{11}.3^3.5^2.13$ Mult = 1 Out = 2

Constructions

Ree, Tits $^2F_4(2) \cong G.2$: the centralizer in $F_4(2)$ of an outer (graph) automorphism of order 2.

This leads to a description of G.2 as the automorphism group of a generalized octagon of order (2,4), which has 1755 "vertices" and 2925 "edges". Each vertex is incident with 5 edges, and each edge with 3 vertices. Tits established the existence of the simple subgroup G of index 2 ($^2F_4(2^n)$ is simple for n > 1).

Rudvalis $^2F_4(2) \cong G.2$: the point stabilizer in the permutation representation of the Rudvalis group (q.v.) on 4060 points, which form a rank 3 graph of valence 1755.

Sz(32)

Suzuki group $Sz(32) \cong {}^2B_2(32)$

Order = 32,537,600 = $2^{10}.5^2.31.41$ Mult = 1 Out = 5

Constructions

Suzuki G : the centralizer in $S_4(32)$ of an outer (graph) automorphism of order 2

G : all 4 x 4 matrices over $\mathbf{F}_{32}$ preserving the set of vectors (t,x,y,z) for which $xy+(x^{s+2}+y^s+z)t=0$, where $s : x \rightarrow x^8$ is the automorphism of $\mathbf{F}_{32}$ with $s^2=2$; projectively this defines an oval of $32^2+1=1025$ points on which G acts doubly transitively.

HS

Sporadic Higman-Sims group HS

Order = 44,352,000 = $2^9.3^2.5^3.7.11$ Mult = 2 Out = 2

Constructions

Graph G.2 : the automorphism group of the graph of D.G.Higman and C.C.Sims, a rank 3 graph of valence 22 on 100 vertices. Any given vertex has 22 neighbours (points), and each of the remaining 77 vertices is joined to 6 of these points, and may be labelled by the corresponding hexad. Two of these 77 vertices are joined just if the corresponding hexads are disjoint. The hexads form a Steiner system S(3,6,22) and the point stabilizer is Aut(S(3,6,22)) ≅ $M_{22}.2$. The simple group G is the subgroup of even permutations.

Higman G : the automorphism group of G.Higman's "geometry" of 176 points P and 176 quadrics Q. The group acts doubly transitively on each set, and each object is incident with 50 of the other type. There are 1100 conics, each of which defines a polarity between the 8 points on it and the 8 quadrics containing it. A quadric and a point on it are polar with respect to just one conic. The intersection of two quadrics is uniquely the union of two conics, which meet in two points. The duality interchanging points and quadrics gives G.2.

Taking M_{22} as the stabilizer of ∞ and 0 in M_{24}, the points are labelled by the octads P containing ∞ but not 0, quadrics by octads Q containing 0 but not ∞, and P is incident with Q just if their intersection has size 0 or 4.

2-graph G : the automorphism group of a 2-graph on 176 points, that is, an assignment of parities to the triples of points, so that the sum of the parities of the four triples in any quadruple is even. Labelling the 176 points by octads as in the previous construction, a triple of octads is even or odd according as the sum of the sizes of their pairwise intersections is 0 or 2 mod 4.

Leech In the Leech lattice (see Co_1) G is the pointwise stabilizer of a triangle OAB of type 233, for instance $O = (0,0,0^{22})$, $A = (5,1,1^{22})$, $B = (1,5,1^{22})$. The setwise stabilizer is G.2.

The 100 vertices V of the Higman-Sims graph are represented by lattice points with VO, VA, VB all of type 2, namely $(4,4,0^{22})$ (1), $(1,1,-3,1^{21})$ (22), $(2,2,2^6 0^{16})$ (77), V and V' being incident in the graph just if type(VV') = 3.

There are 2x176 points P with type(PO) = type(PA) = 2, type(PB) = 3, falling naturally into 176 pairs $\{P_L=(2,0,2^7 0^{15}),\ P_R=(3,1,-1^7 1^{15})\}$ satisfying $P_L+P_R-A = 0$, which correspond to the points of Higman's geometry. The quadrics correspond to the pairs $\{Q_L=(0,2,2^7 0^{15}),\ Q_R=(1,3,-1^7 1^{15})\}$ obtained by interchanging the roles of A and B in the above definition. A point is incident with a quadric just if type($P_i Q_j$) is even.

In the Leech lattice mod 2 the 3-spaces containing the fixed 2-space (of type 233) become points in the quotient 22-dimensional representation over $\mathbb{F}_2$. They are described below by the types of their non-zero vectors.

Presentation G ≅ < 
| $e=(fa)^2$, $1=(cbf)^3=(fdc)^5=(bcde)^4$ >

Remark : 2.G.2 is the involution centralizer in the Harada-Norton group.

J_3

Sporadic Janko group J_3

Order = 50,232,960 = $2^7.3^5.5.17.19$ Mult = 3 Out = 2

Constructions

Unitary (2) 3.G has a 9-dimensional unitary representation over $\mathbb{F}_4 = \{0,1,w,\bar{w}\}$ with basis vectors e(z), where z = x + iy is in $\mathbb{F}_9$. We also write $e(0) = e_\infty$, $e((1-i)^n) = e_n$, i.e.

-1+i	i	1+i
-1	0	1
-1-i	-i	1-i

or

5	2	3
4	∞	0
7	6	1

3.G is the subgroup of the unitary group (for the form $\Sigma x_n\bar{x}_n$) which preserves the subspace S of the exterior square spanned by the 18 vectors $e_ne_{n+4} + e_{n+2}e_{n+6}$, $e_\infty e_0 + e_{n-1}e_{n-3}$, and $we_ne_{n+3} + \bar{w}e_{n-1}e_{n-2}$.

3.G.2 is generated by the maps (specified by the image of e(z)):

$A_Z : w^{Xx+Yy}e(z)$ $B_Z : e(Zz)\ (Z\neq 0)$ $C_Z : e^*(Z/z)\ (Z\neq 0)$

$D_Z : W((z+Z)/z)e(z+Z)$ $E_Z : w^{(X-x)^2+(Y-y)^2}e(z)$ $F_Z : e(\bar{Z}\bar{z})$

where Z = X+iY is in $\mathbb{F}_9$, $e^*(t) = e(it)+e(-it)+e(-t)$, $W(i) = w$, $W(-i) = \bar{w}$, and otherwise W(t) = 1; the map F_Z is antilinear.

There are four orbits {0}, I, II, III on vectors, (e.g. 0, e_∞, e_0+e_4, $e_\infty+e_0+e_4$) the minimal weights of representatives being 0, 1, 2, 3 respectively. The stabilizer of $\langle e_\infty\rangle$ in 3.G is a group $(3^2xA_6).2 \cong 3 \times 3{:}PGL_2(9)$ in which $\langle E_0\rangle$ is normal and A_Z, B_Z, C_Z map to the elements $t \to Z+t$, $t \to Zt$, $t \to Z/t$ of $PGL_2(9)$. The stabilizer in 3.G of $\langle e_\infty+e_0+e_4\rangle$ is $3 \times L_2(17)$, in which the $L_2(17)$ (centralizing F_1) is generated by D_1 and C_{-1}, whose product has order 17. All non-zero isotropic vectors are of type II and the group preserves a symmetrical joining relation between isotropic vectors, the vectors joining v ($\neq 0$) forming a 3-dimensional space J(v). We define $J(U) = \langle J(u){:}u \text{ of type II in } U\rangle$. A type II vector v (e.g. $v = e_0+e_4$) is contained in five 2-spaces (projectively, lines) inside J(v), namely two <u>even</u> ones $\langle v,v'=e_3+e_5\rangle$, $\langle v,v''=e_1+e_7\rangle$ and three <u>odd</u> ones $\langle v,v'+w^nv''\rangle$. There is also a distinguished orbit of <u>special</u> 4-spaces, such as $\langle \bar{w}e_n+we_{n+2} | n=0,1,4,5\rangle$, each the disjoint union of 17 even spaces.

Complex 3.G has an 18-dimensional complex representation writable over $\mathbb{Q}(\sqrt{-3},\sqrt{5})$, for which explicit matrices have been computed. In characteristic 2 this becomes the representation given above on the 18-space S.

U3(11)

Unitary group $U_3(11) \cong {}^2A_2(11)$

Order = $70{,}915{,}680 = 2^5.3^2.5.11^3.37$ Mult = 3 Out = S_3

Constructions

Unitary $GU_3(11) \cong 4 \times 3.G.3$: all 3×3 matrices over $\mathbf{F}_{121}$ preserving a non-singular Hermitian form;

$PGU_3(11) \cong G.3$; $SU_3(11) \cong 3.G$; $PSU_3(11) \cong G$

Remark : G.2 is a maximal subgroup of Janko's group J_4

$O_8^+(2)$

Orthogonal group $O_8^+(2) \cong D_4(2)$

Order = 174,182,400 = $2^{12}.3^5.5^2.7$ Mult = 2^2 Out = S_3

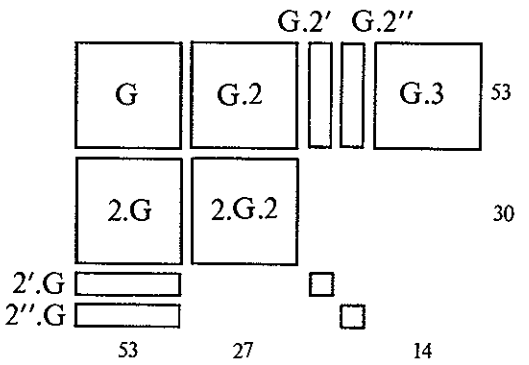
Constructions

Orthogonal $GO_8^+(2) \cong PGO_8^+(2) \cong SO_8^+(2) \cong PSO_8^+(2) \cong G.2$: all 8 x 8 matrices over F_2 preserving a non-singular quadratic form of Witt defect 0, for example $x_1x_2 + x_3x_4 + x_5x_6 + x_7x_8$; $O_8^+(2) \cong G$

Weyl 2.G.2 : the Weyl group of the E_8 root lattice, generated by the 120 reflections in the 240 root vectors, which in the standard base are $(\pm1,\pm1,0,0,0,0,0,0)$ (56) and $(\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2},\pm\frac{1}{2})$ (even sign combinations) (64).
Various other bases are useful, for example that described in the "Cayley" construction below, and that in which the root vectors are $\pm(\frac{2}{3}^3,-\frac{1}{3}^6)^S$ (84) and $(1,-1,0^7)^S$ (36) on 9 coordinates adding to zero.
Reducing mod 2 shows the isomorphism with $O_8^+(2)$.

Cayley $2^2.G$: the isotopy group of the non-associative ring of Cayley integers. The real Cayley algebra is spanned by $i_\infty = 1, i_0,\ldots,i_6$ with the condition that for the sets of subscripts:
$\{\infty,1,2,4\}, \{\infty,2,3,5\}, \{\infty,3,4,6\}, \{\infty,0,4,5\}, \{\infty,1,5,6\}, \{\infty,0,2,6\}, \{\infty,0,1,3\}$
$\langle i_\infty,i_a,i_b,i_c\rangle \equiv \langle 1,i,j,k\rangle$ is a quaternion subalgebra. In this the ring of Cayley integers is the lattice (a scaled copy of the E_8 root lattice) of vectors $\Sigma a_n i_n$ ($n = \infty,0,\ldots,6$) for which all $2a_n$ are in $\mathbf{Z}$ and $\{n:a_n$ in $\mathbf{Z}\}$ is one of:
$\{\}, \{0,1,2,4\}, \{0,2,3,5\}, \{0,3,4,6\}, \{\infty,0,4,5\}, \{0,1,5,6\}, \{\infty,0,2,6\}, \{\infty,0,1,3\}$
or their complements. There are 240 unit Cayley numbers, corresponding to the E_8 root vectors.
An isotopy is a triple of maps (A,B,C) such that $xyz = 1 \Leftrightarrow x^Ay^Bz^C = 1$. There are two such isotopies (A,B,C) and (-A,-B,C) for each determinant 1 symmetry C of the lattice. The isotopy group can be extended to $2^2.G.S_3$ by adjoining the triality automorphism $(A,B,C) \rightarrow (B,C,A)$, and the duality automorphism $(A,B,C) \rightarrow (J^{-1}B^{-1}J, J^{-1}A^{-1}J, J^{-1}C^{-1}J)$ where J is the Cayley conjugation map $x \rightarrow \bar{x}$. The isotopies are generated by (L_u,R_u,B_u), where $L_u : x \rightarrow ux$, $R_u : x \rightarrow xu$, $B_u : x \rightarrow u^{-1}xu^{-1}$ and u ranges over the 240 unit Cayley numbers. The reflection in u is $-J.B_u$.

Presentation 2.G.2 ≅ 



Remark : $G.S_3$ is a maximal subgroup of the Fischer group Fi_{22}

Constructions

Steinberg G : the centralizer in $O_8^+(8)$ of an outer automorphism of order 3.

This leads to a description of G.3 as the automorphism group of a generalized hexagon of order (2,8), consisting of 819 "vertices" and 2457 "edges". Each vertex is incident with 9 edges, and each edge is incident with 3 vertices.

Jordan G.3 is a subgroup of the compact Lie group $F_4(\mathbb{R})$, the automorphism group of the 27-dimensional exceptional Jordan algebra. This consists of 3 x 3 Hermitian matrices

$$\begin{bmatrix} a & C & \bar{B} \\ \bar{C} & b & A \\ B & \bar{A} & c \end{bmatrix} = (a,b,c|A,B,C) \quad (a,b,c \text{ real})$$

over the real Cayley algebra with units i_∞, i_0, ... i_6, in which $i_\infty = 1$, $i_{n+1} \to i$, $i_{n+2} \to j$, $i_{n+4} \to k$ generate a quaternion subalgebra. G.3 is the automorphism group of the set of 819 images (roots) of the idempotents

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} (3) \qquad \begin{bmatrix} 0 & 0 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{bmatrix} (48) \qquad \begin{bmatrix} \frac{1}{2} & \frac{1}{4}s & \frac{1}{4}s \\ \frac{1}{4}s & \frac{1}{4} & \frac{1}{4} \\ \frac{1}{4}s & \frac{1}{4} & \frac{1}{4} \end{bmatrix} (768)$$

under the group $[2^{11}].S_3$ generated by the maps taking (a,b,c,|A,B,C) to

$$(a,b,c|iAi,iB,Ci),\ (b,c,a|B,C,A) \text{ and } (a,c,b|\bar{A},-\bar{C},-\bar{B}) \qquad (*)$$

where $i = \pm i_n$ and $s = \frac{1}{2}\Sigma i_n$. This group extends by $(i_0\ i_1 \ldots i_6)$ to a maximal subgroup of G, and by $(i_1\ i_2\ i_4)(i_3\ i_6\ i_5)$ to a maximal subgroup of G.3. The simple group G is generated by the "reflections" $y \to y + 4((y.r)r - y \times r)$ in the roots, where y x z is the Jordan product $\frac{1}{2}(yz + zy)$ and y.z is the natural inner product corresponding to $\mathrm{Norm}(y) = \Sigma(\mathrm{Norm}(y_{ij}))$. There are 2457 sets of 3 mutually orthogonal roots (bases), and each root is in just 9 bases. By restricting i in (*) to be ±1, we obtain the subgroup $L_2(7)$, while by restricting it to be ±1 or $\pm i_0$, we obtain the subgroup $U_3(3)$. The normalizers of these groups are maximal subgroups of G, and they are related to the complex and quaternionic reflection groups 2 x $L_3(2)$ and 2 x $U_3(3)$ respectively.

Remark : G.3 is a maximal subgroup of Thompson's group.

$L_3(11)$ and A_{12}

Linear group $L_3(11) \cong A_2(11)$

Order = 212,427,600 = $2^4.3.5^2.7.11^3.19$ Mult = 1 Out = 2

Constructions

Linear $GL_3(11) \cong 10 \times G$: all non-singular 3 x 3 matrices over F_{11};

$PGL_3(11) \cong SL_3(11) \cong PSL_3(11) \cong G$

Maximal subgroups					Specifications	
Order	Index	Structure	G.2	Character	Abstract	Linear
1597200	133	$11^2:(5x2L_2(11).2)$	$11_+^{1+2}:10^2$,	1a+132a	$N(11^2)$	point

The characters of $L_3(11)$ are not printed

Alternating group A_{12}

Order = 239,500,800 = $2^9.3^5.5^2.7.11$ Mult = 2 Out = 2

Constructions

Alternating $S_{12} \cong G.2$: all permutations on 12 letters;

$A_{12} \cong G$: all even permutations; 2.G and 2.G.2 : the Schur double covers

Presentations $G \cong \langle x_1,\ldots,x_{10} | x_i^3=(x_ix_j)^2=1\rangle$; $G.2 \cong$ ———————————————

Remark : A_{12} is the largest alternating group involved in the Monster group F_1. It arises in several large groups involved in F_1, notably the Fischer group Fi_{24}' and the Harada-Norton group.

M_{24}

Sporadic Mathieu group M_{24}

Order = 244,823,040 = $2^{10}.3^3.5.7.11.23$ Mult = 1 Out = 1

Constructions

Golay (2) code G : the automorphism group of the (extended) binary Golay code, the unique dimension 12 length 24 code over $\mathbf{F}_2$ of minimal weight 8, which is defined in several ways below. The code and cocode (words modulo the code) have weight distributions $0^1 8^{759} 12^{2576} 16^{759} 24^1$ and $0^1 1^{24} 2^{276} 3^{2024} 4^{1771}$ respectively. The support of a code word is called a C-set, and C-sets of size 8 and 12 are called octads and dodecads respectively. A pair of complementary dodecads is a duum, and a triple of disjoint octads is a trio.

Elements of the cocode are called C*-sets. Their minimal representatives are unique except that each tetrad is one of a set of six disjoint mutually congruent tetrads (forming a sextet).

We usually arrange the coordinates in the 4 x 6 MOG array, which is particularly valuable because it simultaneously exhibits the elements of several distinct maximal subgroups.

Steiner system G : the automorphism group of the Steiner system S(5,8,24) of 759 special octads from a 24-set such that each pentad is in a unique special octad. The octads are the supports of the weight 8 words of the binary Golay code (see above). If $\{a_1,a_2,\ldots,a_8\}$ is any octad, then the number of octads (resp. dodecads) that meet $\{a_1,\ldots,a_i\}$ in precisely $\{a_1,\ldots a_j\}$ is the (j+1)'th entry in the (i+1)'th row of the left (resp. right) table below.

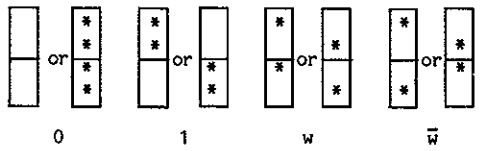
Hexacode In this construction it is easy to recognise codewords and to complete octads from 5 given points. The 64 hexacode words (see A_6) (ab cd ef) are obtained from

0x 0x yz yz yz yz 00 xx xx xx yy zz 00 00 00

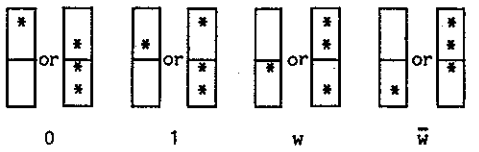
(in which (x,y,z) is any cyclic permutation of $(1,w,\bar{w})$) by freely permuting the three couples ab, cd, ef and reversing the order in any even number of them. The Golay code words are obtained from hexacode words either by giving all their digits even interpretations in any way for which the top row receives an even number of entries, or by giving the digits odd interpretations in any way for which the top row receives an odd number of entries.

even interpretations



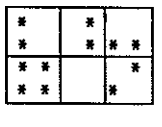
0 1 w $\bar{w}$

odd interpretations

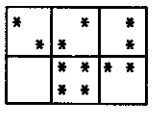


0 1 w $\bar{w}$

We give one even and one odd interpretation of (01 01 $w\bar{w}$):



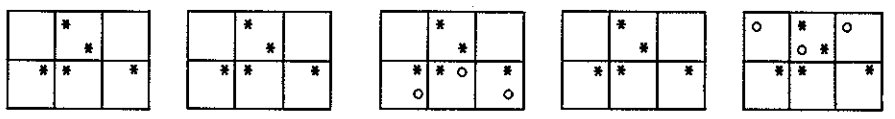
0 1 0 1 w $\bar{w}$



0 1 0 1 w $\bar{w}$

To complete an octad from 5 given points:

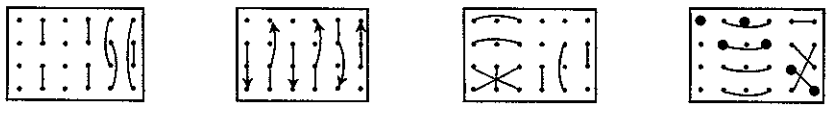
In the example (a) below, if the parity of the answer were even, we must change the three columns ? of (b). So the remaining columns are correct, and the digits below them determine the hexacodeword and trial octad of (c), whose top row has the wrong parity. So the parity is odd, and the digits in (d) determine the hexacodeword and octad as in (e).



(a) 0 ? w ? 0 ? (b) ⇒ 0 1 $\bar{w}$ w 0 1 (c) ? w ? 1 ? w (d) ⇒ 0 w $\bar{w}$ 1 0 w (e)

Using the fact that a hexacodeword is uniquely determined by any 3 correct digits, or by 5 digits of which at most one may be mistaken, the method more generally finds the unique Golay codeword nearest to any given set of odd cardinal. (The method also works for sets of even cardinal, although the answer need not be unique.)

Sextet The group fixing the sextet of MOG columns has structure $2^6{:}3{\cdot}S_6$, the stabilizer of the top row being a subgroup $3{\cdot}S_6$, and the code, as constructed above, is invariant under this group. The elements of the subgroup 2^6 correspond to hexacodewords (a), and there are other correspondences between hexacodewords and the remaining elements of $2^6{:}3$ (b) and the involutions of $3{\cdot}S_6$ (c), (d):



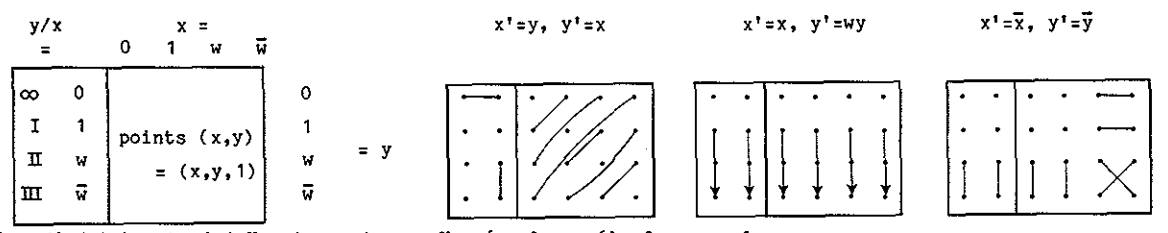
0 1 0 1 w $\bar{w}$ (a) 0 1 0 1 w $\bar{w}$ (b) 0 1 0 1 w $\bar{w}$ (c) 0 1 0 1 w $\bar{w}$ (d)

Triad In terms of the 21 point projective plane over $\mathbb{F}_4 = \{0,1,w,\bar{w}\}$ the octads of the Steiner system are

the points of a line	+	3 extra points I, II, III
a hyperconic	+	2 of I, II, III
an $\mathbb{F}_2$-subplane	+	one of I, II, III

or the points of two lines without their intersection.

Every maximal set of points with no three in line is a hyperconic, consisting of the five points of a conic and the unique point not on any chord. Hyperconics whose equations have coefficients in $\mathbb{F}_2$ mate with {II, III}, while the $\mathbb{F}_2$-subplane of all points with coordinates in $\mathbb{F}_2$ mates with I. An element of $GL_3(4)$ with determinant w effects the permutation (I II III). In fact the construction is invariant under $P\Gamma L_3(4)$, with the field automorphism effecting (II III). In the MOG array below points (x,y,0) in the left-hand octad are denoted y/x, while the points (x,y)=(x,y,1) form the right-hand square. We also show the elements of M_{24} obtained from some elements of $P\Gamma L_3(4)$:



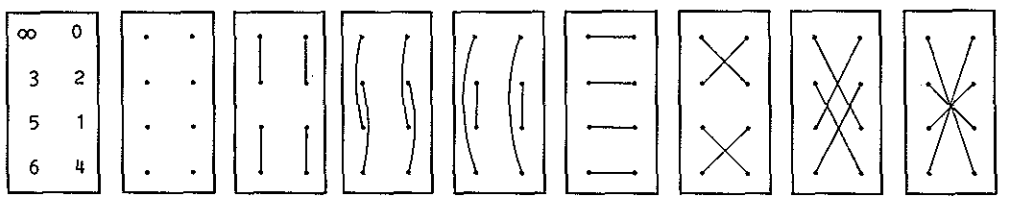
Trio We select two disjoint extended Hamming codes on V = {∞,0,...,6}, for example

(i) {}, {∞, i+3, i+5, i+6}, and complements

(ii) {}, {∞, i+1, i+2, i+4}, and complements

The binary Golay code consists of all words of the form (X+t,Y+t,Z+t) for which X, Y, Z are elements of the first Hamming code with X+Y+Z = {} or V, while t is in the second Hamming code. Using the indicated numbering for each brick of the MOG, this construction exhibits a maximal subgroup $2^6{:}(S_3 \times L_2(7))$ of M_{24} in which the typical element of 2^6 consists of three translations (see below) with trivial product, S_3 permutes the three bricks, and $L_2(7)$ acts on each brick in the same way.

The brick numbering and the translations



The eight 3-sets permuted by the $L_2(7)$ in this construction give rise to 14 dodecads by taking unions. There is one other type of family (octern) of eight 3-sets with this property, whose stabilizer is a maximal subgroup $L_2(7)$, acting transitively.

Octad This construction uses the isomorphism between A_8 and $L_4(2)$, and is only briefly sketched here. The 24 points are taken as the points of an affine 4-space V over $\mathbb{F}_2$ (whose automorphism group is $2^4{:}L_4(2) \cong 2^4{:}A_8$), together with those of the 8-point set S = {1,2,...,8} on which A_8 acts. They can be written in the MOG array thus:

1	5	0	a	b	a+b
2	6	c	a+c	b+c	a+b+c
3	7	d	a+d	b+d	a+b+d
4	8	c+d	a+c+d	b+c+d	a+b+c+d
S		V			

The stabilizer of a system of four parallel 2-spaces in V is also the stabilizer of a bisection of S into two complementary tetrads. The six 4-sets so obtained form one of a family of 35 sextets which suffice to define the code. The 759 octads of S(5,8,24) are the 1 octad S, 280 = 35x2x4 meeting S in 4 points (obtainable from the above sextets), 448 meeting S in 2 points, and the 30 affine 3-spaces in V.

Modulo 23 The binary Golay code is a quadratic residue code, modulo 23. In the projective line PL(23), let Q={0,quadratic residues}, N={∞,non-residues}. The code is spanned by the words $w_\infty = \Sigma e_i$ (all i), $w_t = \Sigma e_{n-t}$ (n in N). We have $\Sigma c_i w_i = 0 \Leftrightarrow (c_i)$ is in the code. G is generated by the elements $A : t \to t+1$, $B : t \to 2t$, $C : t \to -1/t$ and $D : t \to t^3/9$ (t in Q) or $9t^3$ (t in N), in which $\langle A,B,C\rangle \cong PSL_2(23)$ and $\langle A,B,D\rangle \cong M_{23}$.

Mathieu 12 The Mathieu group M_{12} acts on two 12-sets $L=\{n^+\}$, $R=\{n^-\}$, interchanged by its outer automorphism (duality). The stabilizer of a tetrad in one stabilizes a tetrad in the other while the stabilizer of a duad in one stabilizes a pair of complementary hexads in the other. The resulting octads splitting 4+4, 2+6, 6+2 form the Steiner system S(5,8,24). Thus (using the shuffle numbering, see M_{12}) the binary Golay code is spanned by $\{1^+2^+3^+4^+5^+6^+0^-1^-\}$, $\{0^+1^+2^+3^+7^+8^+1^-2^-\}$, $\{0^+1^+2^+4^+5^+9^+2^-3^-\}$, $\{0^+1^+3^+4^+6^+7^+3^-4^-\}$, $\{0^+1^+2^+3^+5^+10^+4^-5^-\}$, $\{0^+1^+2^+4^+6^+8^+5^-6^-\}$, $\{0^+2^+3^+4^+5^+7^+6^-7^-\}$, $\{0^+1^+2^+3^+6^+9^+7^-8^-\}$, $\{0^+1^+3^+4^+5^+8^+8^-9^-\}$, $\{0^+1^+2^+5^+6^+7^+9^-10^-\}$, $\{0^+1^+2^+3^+4^+11^+10^-11^-\}$ and $\{0^+1^+2^+3^+4^+5^+6^+7^+8^+9^+10^+11^+\}$. The shuffle and modulo 23 numberings are related by:

n^+ = whichever of n, −n is in Q n^- = whichever of 8/n, −8/n is in N.

These and the lexicographic numbering (see below) appear in the MOG array as follows:

0	∞	1	11	2	22
19	3	20	4	10	18
15	6	14	16	17	8
5	9	21	13	7	12

0^+	0^-	1^+	7^-	2^+	8^-
2^-	3^+	5^-	4^+	10^-	5^+
1^-	6^+	6^-	7^+	9^-	8^+
3^-	9^+	4^-	10^+	11^-	11^+

d_0	d_4	d_8	d_{12}	d_{16}	d_{20}
d_1	d_5	d_9	d_{13}	d_{17}	d_{21}
d_2	d_6	d_{10}	d_{14}	d_{18}	d_{22}
d_3	d_7	d_{11}	d_{15}	d_{19}	d_{23}

Lexicographic Each code word can be defined in succession as the lexicographically earliest word $(d_0,\ldots,d_{23})$ differing in at least 8 places from all its predecessors:

(0^{24}) $(0^{16}1^8)$ $(0^{12}1^4 0^4 1^4)$ ... (1^{24})

$G_2(4)$

Chevalley group $G_2(4)$

Order = 251,596,800 = $2^{12}.3^3.5^2.7.13$ Mult = 2 Out = 2

Constructions

Chevalley $G_2(4) \cong G$: the adjoint Chevalley group of type G_2 over $\mathbb{F}_4$;

G.2 : the automorphism group of a generalized hexagon of order (4,4), consisting of 1365 vertices and 1365 edges, each object being incident with 5 of the other type.

Cayley G : the automorphism group of the $\mathbb{F}_4$ Cayley algebra, the tensor product of the field $\mathbb{F}_4 = \{0,1,w,\bar{w}\}$ with the non-associative ring of Cayley integers. Calculations are complicated by the fact that there is no very symmetric base for the Cayley integers. They can be generated (in $\mathbb{R}^8$) by the even sums of X_∞, X_0, ..., X_6 together with $1 = \frac{1}{2}\Sigma X_n$, with multiplication defined by the equations $2X_n^2 = X_n - 1$, $2X_0X_\infty = 1-X_1-X_2-X_4$, $2X_\infty X_0 = 1-X_3-X_5-X_6$ and their images under $L_2(7)$. Additively, this is a scaled copy of the E_8 root lattice under the norm $N(\Sigma a_n X_n) = \frac{1}{2}\Sigma a_n^2$. Each $\mathbb{F}_4$ Cayley number has the form A+wB where A and B are Cayley integers modulo doubles of Cayley integers. (Note: since X_n is not a Cayley integer, $2X_n$ is not 0 in this algebra.) There are 1 + 4095 + 2080x2 + 2016x4 elements of determinant 1, with respective orders 1, 2, 3 and 5. The elements of order 2 fall into 1365 triples of the form $\{1+X, 1+wX, 1+\bar{w}X\}$. The map $X \rightarrow A^{-1}XA$ is an automorphism of the algebra just if A has order 3 (or 1). There is a subgroup isomorphic to the Hall-Janko group J_2 containing 280x2 of these maps.

Quaternionic 2G : the automorphism group of the quaternionic Leech lattice, whose typical element is written $(q_\infty;q_0,\ldots,q_4)$. The quaternions ±1, ±i, ±j, ±k, $w = \frac{1}{2}(-1+i+j+k)$ multiplicatively generate a group $2A_4$ and additively generate the Hurwitz ring of integral quaternions. The lattice is closed under the scalar left multiplications by these numbers. There is a monomial group $2^{5+6}.(3xA_5)$ (acting on the right) generated by diag(i;i,j,k,k,j), diag(w;w,w,w,w,w), $(q_\infty)(q_0\ q_1\ \ldots\ q_4)$ and $(q_\infty\ q_0)(q_1\ q_4)$. There are 196560 = 24 x 8190 minimal vectors, which generate 8190 1-spaces, and span the lattice. They are the images under the monomial group of $(2+2i;0^5)$ (6), $(2;2,0^4)$ (120), (0;0,1+k,1+j,1+j,1+k) (1920), $(i+j+k;1^5)$ (6144), and fall naturally into 1365 congruence bases mod <1+i>. The corresponding basic decompositions, such as $\langle e_\infty\rangle\oplus\ldots\oplus\langle e_4\rangle$ each refine 5 trio decompositions such as $\langle e_\infty,e_0\rangle\oplus\langle e_1,e_4\rangle\oplus\langle e_2,e_3\rangle$, which in turn each refine to 5 basic decompositions.

The quaternionic form of a real Leech lattice vector is obtained by interpreting the columns of the MOG as the quaternion coordinates of a vector $(q_\infty;q_0,\ldots,q_4) = \Sigma q_t e_t$, according to the scheme:

q_∞	q_0	q_1	q_2	q_4	q_3
1	1	1	1	1	1
k	j	k	j	k	j
i	k	i	k	i	k
j	i	j	i	j	i

and then dividing by 2.

The unit group $2A_4$ extends in $2Co_1$ to $2A_5$, which additively generates the icosian ring of integral quaternions, and converts the lattice into a 3-dimensional module over this ring, whose automorphism group is $2J_2$ (q.v.). The subgroup $3L_3(4)$ can be written over the complex subring $\mathbb{Z}[w]$.

Graph G.2 : the automorphism group of a rank 3 graph of valence 100 on 416 points, in which the point stabilizer is $J_2.2$.

Presentations G.2 $\cong$ < a b c 8 d e f g | $a=(cd)^4,(bcde)^8=1$ >

G $\cong$ < e d 8 c b f | $a=(cd)^4, 1=(abf)^5=(abcf)^5=(abcdecbdc)^7[=(abc)^5]$ >
5
a

Remark : $G_2(4)$ is a maximal subgroup of the Suzuki group, and contains the Hall-Janko group J_2.

M^cL

Sporadic McLaughlin group M^cL

Order = 898,128,000 = $2^7.3^6.5^3.7.11$ Mult = 3 Out = 2

Constructions

Graph G.2 : the automorphism group of the McLaughlin graph, a rank 3 graph of valence 112 on 275 points in which the point stabilizer is $U_4(3).2$. Under the simple group G, the 2-point stabilizers are $L_3(4)$ and $3^4{:}A_6$, and there are two families of 22-point cocliques stabilized by M_{22}, and interchanged by the outer automorphism.

Leech G : the pointwise stabilizer of a triangle ABC of type 322 in the Leech lattice (see Co_1). G.2 : the setwise stabilizer. The 275 vertices V of the McLaughlin graph are represented by the lattice points for which VA, VB, VC are all of type 2, and V is joined to V' in the graph just when VV' has type 3. Taking A = $(0,0,0^{22})$, B = $(4,4,0^{22})$, C = $(5,1,1^{22})$ these points are $(4,0,4,0^{21})$ (22), $(2,2,2^6 0^{16})$ (77) and $(3,1,-1^7 1^{15})$ (176), and the containment of M_{22} is visible.

In the Leech lattice modulo 2, the 3-spaces containing the fixed 2-space (of type 223) become points in the quotient 22-dimensional representation over $\mathbb{F}_2$. They are described below by the types of their non-zero vectors. The remaining maximal subgroups arise as intersections of G with maximal subgroups of Co_1 (q.v.).

Unitary (5) 3.G has a 45-dimensional unitary representation written over $\mathbb{F}_{25}$. Explicit matrices have been computed.

Presentation 3.G ≅ <  | $a=(cf)^2, b=(ef)^3, 1=(eab)^3=(bce)^5=(aecd)^4=(cef)^{21}$ > ; for G adjoin $(cef)^7=1$

Remark : 3.G.2 is a maximal subgroup of the Lyons group.

Sporadic Held group He ≅ F_7

Order = 4,030,387,200 = $2^{10}.3^3.5^2.7^3.17$ Mult = 1 Out = 2

Constructions

Held G : the automorphism group of a directed graph of rank 5 and out-valence 136 on 2058 points; the point stabilizer is $S_4(4).2$, and the suborbit lengths are 1, 136, 136, 425, 1360. The outer automorphism reverses the directions of the edges, thereby fusing the two orbits of size 136. The centralizer of a 2B-involution is isomorphic to the centralizers of suitable involutions in $L_5(2)$ and M_{24}.

Monster 7 x G : the centralizer in the Monster group F_1 (q.v.) of an element of class 7A. The normalizer is (7.3 x G).2. An element of order 3 in the normal subgroup 7.3 of this is centralized by $3.Fi_{24}'$, and this leads to an embedding of G.2 in Fi_{24}'. The group G has been explicitly constructed as the subgroup of Fi_{24}' stabilizing a set of 2058 3-transpositions in Fi_{24}.

Presentations G.2 ≅ <  | $g=(ef)^4=(abc)^3,a=(cd)^5,1=(cdefef)^4$ >

Orthogonal group $O_7(3) \cong B_3(3)$

Order = 4,585,351,680 = $2^9.3^9.5.7.13$ Mult = 6 Out = 2

Constructions

Orthogonal $GO_7(3) \cong 2 \times G.2$: all 7 x 7 matrices over $\mathbb{F}_3$ preserving a non-singular quadratic form;

$PGO_7(3) \cong SO_7(3) \cong PSO_7(3) \cong G.2$; $O_7(3) \cong G$

Complex 3.G has a 27-dimensional complex unitary representation over $\mathbb{Z}[w]$ ($w = z3$), in which there is an orbit of 3 x 378 root vectors. It is simplest to take 28 coordinates indexed by unordered pairs from the 8-set {1,2,3,4,5,6,7,8} and work modulo the 1-space $\langle(1^{28})\rangle$. The norm of the vector $(x_{12},\ldots,x_{78})$ is $\Sigma|x_{ij}|^2/4 - |\Sigma x_{ij}|^2/112$. The root vectors are the multiples by powers of w of the following vectors of shape $(\theta^2,1^{10},0^{16})$, where $\theta = w-\bar{w} = i3$:

(i) θ on ac, bc, and 1 on ad, bd, ae, be, af, bf, ag, bg, ah, bh

(ii) θ on ab, cd, and 1 on ac, bd, ad, bc, ef, gh, eg, fh, eh, fg

The subgroup $S_6(2)$ permutes the coordinates (see $S_6(2)$, "Hesse"). There is an invariant multiplication x*y antilinear in each coordinate, and 3.G.2 is generated by the antilinear maps ("reflections") $x \longrightarrow x^r = x*r - \langle r,x\rangle r$ as r ranges over the root vectors. The square of a coordinate vector is (2-11w)/27 times itself, and the product of two distinct coordinate vectors has the form $(A^2,B^{10},0^{16})$, where $A = (7\bar{w}-4)/216$, $B = \bar{w}/8$, and the coordinates are distributed as in the corresponding root vector. The reduction modulo 2 of this representation extends to $3Fi_{22}$ and $3\cdot({}^2E_6(2)).3$.

Remark : The Fischer group Fi_{22} contains two conjugacy classes of maximal subgroups isomorphic to $O_7(3)$.

Presentation $3.G \cong \langle$ a b c d e f | $(abcdefg)^9=1$ $\rangle$; replacing the last relation by

g
h

$(bcdefdghd)^{10}=1$ gives 2 x G; both relations give G. See page 232.

Symplectic group $S_6(3) \cong C_3(3)$

Order = 4,585,351,680 = $2^9.3^9.5.7.13$ Mult = 2 Out = 2

Constructions

Symplectic $Sp_6(3) \cong 2.G$: all 6 x 6 matrices over F_3 preserving a non-singular symplectic form;

$PSp_6(3) \cong S_6(3) \cong G$

Complex The automorphism group of the extraspecial group 3_+^{1+6} is $3^6{:}2S_6(3).2$. A faithful 27-dimensional representation of 3_+^{1+6} extends to a representation of $3_+^{1+6}{:}2S_6(3).2$ in which an involution in the normal subgroup $3_+^{1+6}.2$ has eigenspaces of dimensions 13 and 14. This leads to constructions of G and 2.G respectively as 13- and 14-dimensional groups of complex matrices.

$G_2(5)$

Chevalley group $G_2(5)$

Order = 5,859,000,000 = $2^6.3^3.5^6.7.31$ Mult = 1 Out = 1

Constructions

Chevalley $G_2(5) \cong G$: adjoint Chevalley group of type G_2 over $\mathbb{F}_5$;
the automorphism group of a generalized hexagon of order (5,5), consisting of 3906 "vertices" and 3906 "edges", each object being incident with 6 of the other type;

Cayley G : the automorphism group of the Cayley algebra modulo 5, consisting of vectors $\Sigma a_n i_n$, with a_n in $\mathbb{F}_5$ (subscripts modulo 7), where n runs over $\{\infty,0,\ldots,6\}$ and $i_\infty=1$, $i_{n+1} \to i$, $i_{n+2} \to j$, $i_{n+4} \to k$ form a quaternion subalgebra.

Remark : $G_2(5)$ is a maximal subgroup of the Lyons group.

$U_6(2)$

Unitary group $U_6(2) \cong {}^2A_5(2)$

Order = 9,196,830,720 = $2^{15}.3^6.5.7.11$ Mult = $2^2 \times 3$ Out = S_3

Constructions

Unitary $GU_6(2) \cong 3.G.3$: all 6 x 6 matrices over $\mathbb{F}_4$ preserving a non-singular Hermitian form;

$PGU_6(2) \cong G.3$; $SU_6(2) \cong 3.G$; $PSU_6(2) \cong G$

the transvections $x \longrightarrow x + (x.v)v$ (v isotropic) are the Fischer transpositions (see below).

Graphs $G.S_3$: the automorphism group of a rank 3 graph A of valence 176 on 672 points, a rank 3 graph B of valence 180 on 693 points, and a rank 4 graph C of valence 42 on 891 points. In the unitary geometry the vertices of the graphs A and B are the non-isotropic and isotropic points respectively, and are joined if they are orthogonal. The graph C is described under the Leech lattice construction below.

Leech G : the pointwise stabilizer of a triangle ABC of type 222 in the Leech lattice (see Co_1). $G.S_3$: the setwise stabilizer. There are 891 lattice points V for which VA, VB, VC all have type 2, which form a 42-valent rank 4 graph when we join orthogonal vectors. Taking $A = (0,0,0,0^{21})$, $B = (4,-4,0,0^{21})$, $C = (4,0,-4,0^{21})$, these vectors fall into four sets: $(0,-4,-4,0^{21})$ (1), $(4,0,0,\pm4,0^{20})$ (42), $(2,-2,-2,\pm2^5 0^{16})$ (336), $(3,-1,-1,\pm1^{21})$ (512), which are the orbits of a point-stabilizer $2^9{:}M_{21}$ (in G).

In the Leech lattice modulo 2, the 3-spaces containing the fixed 2-space (of type 222) become points in the quotient 22-dimensional representation over $\mathbb{F}_2$. They are described below by the types of their non-zero vectors.

Fischer $2Fi_{21} \cong 2.G$: the centralizer of a 3-transposition in Fi_{22} (q.v.);

$Fi_{21} \cong G$ is generated by a conjugacy class of 693 involutions, which are 3-transpositions; i.e. any non-commuting pair has product of order 3. These involutions form the above rank 3 graph of valence 180 when commuting involutions are joined. The automorphism group of this graph is $G.S_3$, and the point stabilizer (in G) is $2^{1+8}U_4(2)$.

Presentation See page 232.

R(27)

| | ; | @ | @ | @

R(27) and $S_8(2)$

Ree group $R(27) \cong {}^2G_2(27)$

Order = 10,073,444,472 = $2^3.3^9.7.13.19.37$ Mult = 1 Out = 3

Constructions

Ree G : the centralizer in $G_2(27)$ of an outer automorphism of order 2;

G acts doubly transitively on $27^3 + 1 = 19684$ points, preserving a Steiner system S(2,28,19684) of 512487 blocks of 28 points, any two points being in a unique block.

The elements of the Sylow 3-group of R(q) can be parametrized by triples (x,y,z) of elements of $\mathbf{F}_q$ with the multiplication law

$$(x,y,z)(X,Y,Z) = (x + X , y + Y + xX^s - x^sX , z + Z + yX + x^sX^2 + xX^{s+1} - x^2X^s),$$

where s = 9 for q = 27, and $s = 3^{n+1}$ for $q = 3^{2n+1}$. The stabilizer of a point P is the Sylow 3-normalizer, and the above names can also be used for the points other than P, on which the Sylow 3-group acts by right multiplication. To obtain the normalizer, adjoin the elements taking (x,y,z) to (xt , yt^{s+1} , zt^{s+2}) for non-zero t in $\mathbf{F}_q$.

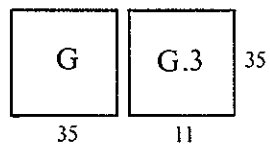
Specifications



Symplectic group $S_8(2) \cong B_4(2) \cong O_9(2)$

Order = 47,377,612,800 = $2^{16}.3^5.5^2.7.17$ Mult = 1 Out = 1

Constructions

Symplectic $Sp_8(2) \cong PSp_8(2) \cong S_8(2) \cong G$: all 8 x 8 matrices over $\mathbf{F}_2$ preserving a non-singular symplectic form.

The subgroup S_{10} is exhibited by taking the 8-dimensional space to be the even weight vectors in $\mathbf{F}_2^{10}$ modulo complementation, with symplectic form $\Sigma x_i y_i$.

Orthogonal $GO_9(2) \cong PGO_9(2) \cong SO_9(2) \cong PSO_9(2) \cong O_9(2) \cong G$: all 9 x 9 matrices over $\mathbf{F}_2$ preserving a non-singular quadratic form. In the 10-coordinate notation above, the 120 triples {i,j,k} correspond to the minus hyperplanes $x_i+x_j+x_k=0$, while the 10+126 sets of size 1 or 5 (modulo complementation) correspond similarly to the plus hyperplanes.

Remark : G is a maximal subgroup of the Fischer group Fi_{23}. For a presentation, see page 232.

Constructions

Lattice 4.G = 2.(2 x G) : the automorphism group of a certain 28-dimensional lattice over $\mathbb{Z}[i]$. There is a monomial group $(2^6{:}U_3(3)){:}2 \cong 2^6{\cdot}G_2(2)$ which may be constructed as follows. Modulo scalars, there are 28 non-zero isotropic vectors v in a unitary 3-space over $\mathbb{F}_9$. The square of a non-zero element c of $\mathbb{F}_9$ is a fourth root of unity which can be lifted to the complex number $c^{[2]} = \pm 1$ or $\pm i$, and we take coordinate vectors e_v with the understanding that $e_{cv} = c^{[2]}e_v$. Using the Hermitian form $x_1\bar{x}_3+x_2\bar{x}_2+x_3\bar{x}_1$ the 28 coordinate vectors may be taken as $e(\infty) = e_{(0,0,1)}$, $e(z,t) = e_{(1,z,z\bar{z}+it)}$ (z in $\mathbb{F}_9$, t in $\mathbb{F}_3$). The element T of $U_3(3)$ acts by $e_v \longrightarrow e_{vT}$, and the element taking $e(\infty) \longrightarrow e(\infty)$, $e(z,t) \longrightarrow e(\bar{z},-t)$ extends this to the full monomial group $2^6{\cdot}G_2(2)$. The 4x4060 minimal vectors are the images under this group of

$e_a+e_b+e_{a+b}+e_{a-b}$ (a, b, a+b, a-b distinct isotropic vectors)

$\frac{1}{2}e(\infty) + \frac{1}{2}\Sigma\,[\ e(t,0)+e(t-i,t)-e(i-t,t)-ie(t,1)-ie(t,-1)\ ]$ (summed over t in F_3)

$[\ (1-2i)e(\infty) + \Sigma e(z,t)\ ]\ /\ (2+2i)$ (summed over z in $\mathbb{F}_9$, t in $\mathbb{F}_3$)

The vectors $(2+2i)e_v$ form a congruence base modulo 1+i. The group is transitive on sets of 3 minimal vectors with given inner products, except that 3 mutually orthogonal vectors may belong to a quartet, or to a dozen but no quartet, or to a base but no dozen (see below). There are 10 minimal vectors fixed by an element of class 3A, which form a decad with all inner products 1. There are also maximal heptads of 7 minimal vectors with all inner products 1. Each of these is one of a set of 50, whose sums are all congruent modulo 5, and which form a copy of the Hoffman-Singleton graph (see $U_3(5)$) when intersecting heptads are joined.

Graph G : the automorphism group of a rank 3 valence 2304 graph on 4060 points, in which the point stabilizer is ${}^2F_4(2)$. The vertices of the graph are the minimal vectors considered modulo the unit scalar factors ±1, ±i. These have norm 4; a vertex is joined (inner product ±1 or ±i) to 2304 others, and disjoined (orthogonal) to the remaining 1755. Four mutually orthogonal vertices form a quartet if any further vertex orthogonal to three of them is orthogonal to the fourth. Any pair (a_∞,b_∞) of orthogonal vertices lies in five such quartets, forming a dozen $(a_\infty,b_\infty;a_0,b_0;\ldots;a_4,b_4)$ in which any two of the pairs (a_t,b_t) form a quartet. The stabilizer of a dozen is a group $[2^{11}]PGL_2(5)$ in which $PGL_2(5)$ permutes the 6 pairs (a_t,b_t). Any quartet lies in three dozens, whose union consists of 28 mutually orthogonal vertices which can be used to define a base for the 28-space.

Orthogonal (2) Modulo 1+i the lattice yields a 28-dimensional orthogonal representation over $\mathbb{F}_2$, in which many of the vector stabilizers are maximal subgroups. In the table n(z) denotes the reduction of a sum of n minimal vectors, among which the inner product of every pair is z or $\bar{z}$.

Sporadic Suzuki group Suz

Order = 448,345,497,600 = $2^{13}.3^7.5^2.7.11.13$ Mult = 6 Out = 2

Constructions

Graph G.2 : the automorphism group of the Suzuki graph, a rank 3 valence 416 graph on 1782 vertices, in which the point stabilizer is $G_2(4).2$. This graph is the culmination of the Suzuki chain, which includes the rank 3 graphs with automorphism groups $G_2(4).2$, $J_2.2$ and $U_3(3).2$.

Leech 6.G : the automorphism group of the complex Leech lattice. Using the modulo 11 definition of the ternary Golay code (see M_{12}), the lattice consists of all 12-dimensional vectors $(x_\infty,x_0,\ldots,x_9,x_X)$ over $Z[w]$, where $w = z3$, for which there is a Golay code word $(c_\infty,\ldots,c_X)$ and a number $m = 0$, 1 or -1, such that

(i) all $x_t \equiv m \pmod{\theta}$, where $\theta = w - \bar{w} = i3$

(ii) $x_t \equiv m + c_t.\theta \bmod 3$

(iii) $\Sigma x_t \equiv -3m \bmod 3\theta$.

Over Z the lattice becomes the 24-dimensional real Leech lattice and the standard norm $\frac{1}{9}\Sigma x_i\bar{x}_i$ becomes the type (see Co_1). The group is transitive on the minimal vectors and the stabilizer is $U_5(2)$. Modulo θ every vector is congruent to just one of:

(i) the zero vector

(ii) 3 proportional vectors $w^i v$, with v of type 2

(iii) 3x12 vectors $w^i v_1, \ldots, w^i v_{12}$, with v_i mutually orthogonal type 3 vectors.

In the real Leech lattice the stabilizer of the set of vectors $\pm w^i(3\theta,0^{11})^S$ is a group $2 \times 3^6{:}2M_{12}$ in which the subgroup $2 \times 3^6{:}2$ is generated by the maps taking (x_i) to $(-x_i)$, $(w^{c_i}x_i)$, and $(\bar{x}_i)$, for (c_i) in the Golay code. The subgroup of this group preserving the complex lattice structure (and so in 6.G) is the centralizer of $(x_i) \longrightarrow (wx_i)$, namely a group $2 \times 3^6{:}M_{11}$, in which there is a subgroup M_{11} of pure permutations acting transitively on the coordinates. The unit scalars $\pm w^i$ can be regarded as a fixed-point-free subgroup $2A_3$ of $2Co_1$, which can be extended to fixed-point-free groups $2A_4$ and $2A_5$, which yield the quaternionic and icosian Leech lattices (see $G_2(4)$ and J_2). Various maximal subgroups arise by intersecting 6G with maximal subgroups of $2Co_1$, and are labelled correspondingly below.

Presentation 3.G.2 ≅ < a b c 8 d e f g h | a=(cd)^4, (bcde)^8=1 >; for G.2 adjoin (bcdcdefgh)^{13}=1.

3.G.2 ≅ < e d 8 c b f 8 g | a=(cd)^4=(fg)^4, 1=(abcf)^5=(abcdecbdc)^7 >; for G.2 adjoin (bfgfg)^5=1.

Constructions

Graph G has been explicitly constructed as a permutation group. There are two permutation representations on 122760 points (black and white) which can be regarded as the vertices of a bipartite graph of valence 456, whose automorphism group is G.2, the outer automorphism interchanging black points and white points. The point stabilizer is $L_3(7):2$ and the suborbit lengths are 1, 5586, 6384, 52316, 58653 (on black points), and 456, 11172, 32928, 78204 (on white points). The edge stabilizer in G.2 is $7_+^{1+2}:(3 \times D_{16})$.

Modulo 7 3.G has two 45-dimensional representations over $\mathbb{F}_7$ on spaces V and W which are interchanged by the outer elements of 3.G.2, and spanned by vectors V_{mn} and W_{mn} (m,n in {0,1,2,3,4,5,6,7,8,9,X}) that satisfy $V_{mn} + V_{nm} = 0 = \Sigma_m V_{mn}$ and $W_{mn} + W_{nm} = 0 = \Sigma_m W_{mn}$.

The group 3.G.2 is generated by the subscript permutations

A = (0123456789X) B = (13954)(267X8) C = (3945)(26X7)

together with the involution D which takes

$$V_{ab} \longrightarrow -2W_{ab} + (-W_{ai} + 2W_{ac} - 2W_{bc} + 2W_{ic} - 2W_{jc} + W_{ec})(1-P+P^2-P^3+P^4-P^5)$$

$$W_{ab} \longrightarrow 3V_{ab} + (3V_{ai} - 2V_{ac} + 2V_{bc} + 3V_{ic} - 3V_{jc} + 3V_{ec})(1-P+P^2-P^3+P^4-P^5)$$

whenever a,b,c,d,e,f,g,h,i,j,k is an arithmetic progression modulo 11 in which b-a is a quadratic residue, and P is the permutation (ab)(cdhgek)(fij). The elements A, B, C generate M_{11}, and D commutes with $\langle A,B,C^2\rangle = L_2(11)$.

Each space supports an invariant skew-symmetric trilinear form with

$[V_{qr},V_{rs},V_{qs}] = 1$	$[V_{qr},V_{rs},V_{st}] = 1$	$[V_{qr},V_{rs},V_{tu}] = 1$
$[V_{qr},V_{qs},V_{tu}] = 2$	$[V_{Zq},V_{ru},V_{st}] = 4$	$[V_{ZQ},V_{RU},V_{ST}] = 3$
$[W_{qr},W_{rs},W_{qs}] = 6$	$[W_{qr},W_{rs},W_{st}] = 6$	$[W_{qr},W_{rs},W_{tu}] = 0$
$[W_{qr},W_{qs},W_{tu}] = 3$	$[W_{Zq},W_{ru},W_{st}] = 5$	$[W_{ZQ},W_{RU},W_{ST}] = 0$

whenever (qrstu)(QRSTU)(Z) is in M_{11}, and {Q,R,S,T,U} in S(4,5,11). Values at triples of basis elements not derivable from these by the skew-symmetry of the form and the relations $V_{mn} = -V_{nm}$, $W_{mn} = -W_{nm}$, are zero.

"Presentations" 3.G ≅ <  | $(def)^5=1,(cde)^5=a=(cf)^2$, more relations? >

(3.G.2 is obtained by adjoining g such that $(fg)^4=e$, g commutes with a,b,c,d,e, and c commutes with $(dfgfg)^5$)

Constructions

2-graph G : the automorphism group of a 2-graph on 276 vertices, that is, an assignment of parities to the triples of vertices, so that the sum of the parities of the four triples in any quadruple is even. The 276 vertices may be taken as the 23 points and 253 heptads of S(4,7,23) (see M_{23} and M_{24}). The parity of a triple of points and/or heptads is found by counting 1 for each point not in a heptad, or pair of heptads intersecting in 1 point.

Leech G : the stabilizer of a type 3 vector V in the Leech lattice. Taking V = $(5,1^{23})$, O = $(0,0^{23})$, the 552 lattice points P with type(VP) = type(OP) = 2 fall naturally into 276 pairs $\{P_L,P_R\}$ with $P_L+P_R-V = O$, namely $\{ (4,4,0^{22}), (1,-3,1^{22}) \}$ (23) and $\{ (2,2^7 0^{16}), (3,-1^7 1^{16}) \}$ (253), forming the 2-graph described above when the parity of a triple $\{A_L,A_R\}$ $\{B_L,B_R\}$ $\{C_L,C_R\}$ is that of type(A_LB_L) + type(B_LC_L) + type(C_LA_L).

Considering the Leech lattice modulo 2, the 2-spaces containing V become points in the quotient 23-dimensional representation over $\mathbb{F}_2$. They are described below by the types of their non-zero vectors. In all cases except those marked * these vectors lift to real Leech lattice vectors of the appropriate types adding to O.

$O_8^+(3)$

Orthogonal group $O_8^+(3) \cong D_4(3)$

Order = 4,952,179,814,400 = $2^{12}.3^{12}.5^2.7.13$ Mult = 2^2 Out = S_4

Constructions

Orthogonal $GO_8^+(3) \cong 2.G.(2^2)_{122}$: all 8 x 8 matrices over $\mathbb{F}_3$ preserving a quadratic form of Witt defect 0, for example $x_1^2+x_2^2+x_3^2+x_4^2+x_5^2+x_6^2+x_7^2+x_8^2$; $PGO_8^+(3) \cong G.(2^2)_{122}$; $SO_8^+(3) \cong 2.G.2_1$; $PSO_8^+(3) \cong G.2_1$; $O_8^+(3) \cong G$

Cayley $2^2.G.(2^2)_{111}$: the isotopy group of the Cayley algebra modulo 3. An isotopy is a triple of maps (A,B,C) such that $xyz = 1 \Leftrightarrow x^A y^B z^C = 1$. The maps that arise are the linear maps that preserve or negate the quadratic form, and there are two isotopies (A,B,C) and (-A,-B,C) for each such map C. The isotopy group can be extended to $2^2.G.2^2.S_3 \cong 2^2.G.S_4$ by adjoining the triality automorphism $(x,y,z) \longrightarrow (y,z,x)$ and the duality automorphism $(x,y,z) \longrightarrow (\bar{y},\bar{x},\bar{z})$.

Transposition $G.2_2$ and $G.S_3$ are 3-transposition groups, that is, they are generated by a class of involutions in which every pair has product of order at most 3. The transpositions are reflections in one of the orthogonal representations.

Remark : $S_3 \times G.S_3$ and $G.S_4$ are maximal subgroups of Fi_{24} and the Baby Monster, respectively. For a presentation, see page 232.

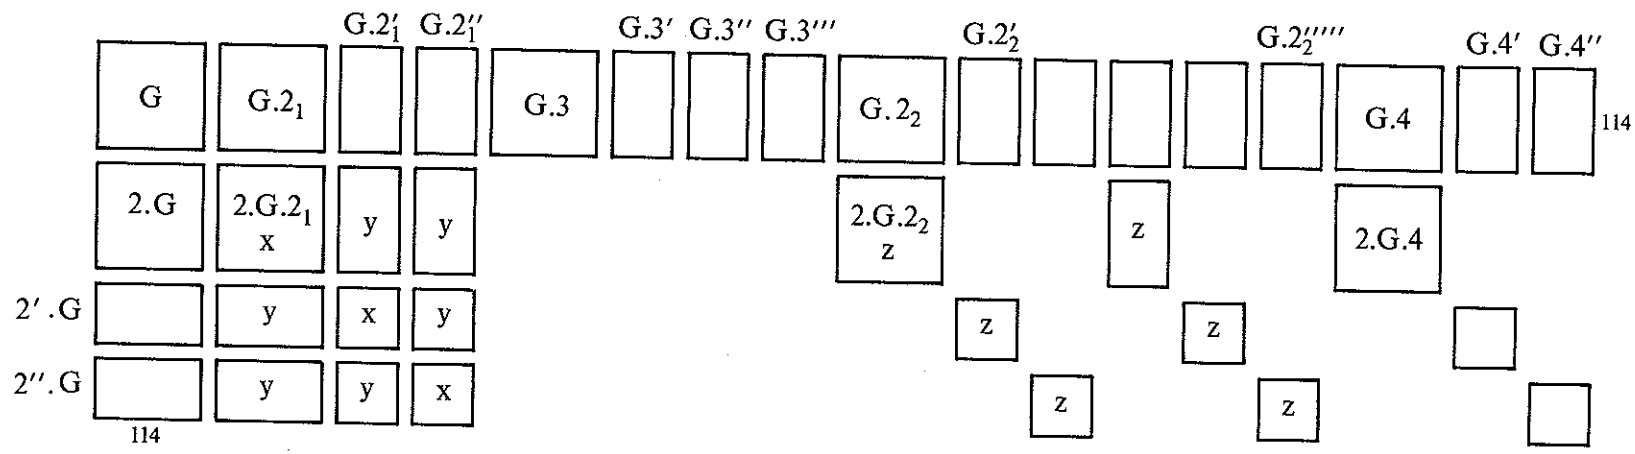
$O_8^+(3)$ and $O_8^-(3)$



Note:- Only the characters of the simple group been printed (pp 136–139). The letters x,y,z indicate that there are just three isoclinism classes of groups 2.G.2, which may be expected to have essentially distinct tables.

Orthogonal group $O_8^-(3) \cong {}^2D_4(3)$

Order = 10,151,968,619,520 = $2^{10}.3^{12}.5.7.13.41$ Mult = 2 Out = 2^2

Constructions

Orthogonal $GO_8^-(3) \cong 2 \times G.2_1$: all 8 x 8 matrices over $\mathbb{F}_3$ preserving a quadratic form of Witt defect 1, for example $x_1^2+x_2^2+x_3^2+x_4^2+x_5^2+x_6^2+x_7^2-x_8^2$; $PGO_8^-(3) \cong G.2_1$; $SO_8^-(3) \cong 2 \times G$; $PSO_8^-(3) \cong O_8^-(3) \cong G$.

Remark : There is a maximal subgroup $3^{8}{\cdot}O_8^-(3){\cdot}2$ in the Monster group F_1.

Maximal subgroups (believed to be complete)

$O_{10}^{+}(2)$

Orthogonal group $O_{10}^{+}(2) \cong D_5(2)$

Order = 23,499,295,948,800 = $2^{20}.3^5.5^2.7.17.31$ Mult = 1 Out = 2

Constructions

Orthogonal $GO_{10}^{+}(2) \cong PGO_{10}^{+}(2) \cong SO_{10}^{+}(2) \cong PSO_{10}^{+}(2) \cong G.2$: all 10 x 10 matrices over $\mathbb{F}_2$ preserving a non-singular quadratic form of Witt defect 0, for example $x_1x_2+x_3x_4+x_5x_6+x_7x_8+x_9x_{10}$; $O_{10}^{+}(2) \cong G$

Remark : There is a maximal subgroup $2^{10+16}O_{10}^{+}(2)$ in the Monster group F_1.

$O_{10}^{-}(2)$

Orthogonal group $O_{10}^{-}(2) \cong {}^2D_5(2)$

Order = 25,015,379,558,400 = $2^{20}.3^6.5^2.7.11.17$ Mult = 1 Out = 2

Constructions

Orthogonal $GO_{10}^{-}(2) \cong PGO_{10}^{-}(2) \cong SO_{10}^{-}(2) \cong PSO_{10}^{-}(2) \cong G.2$: all 10 x 10 matrices over $\mathbf{F}_2$ preserving a quadratic form of Witt defect 1, for example $x_1^2+x_1x_2+x_2^2+x_3x_4+x_5x_6+x_7x_8+x_9x_{10}$; $O_{10}^{-}(2) \cong G$.

By taking the 10-space as all even weight length 12 vectors over $\mathbf{F}_2$ modulo complementation, we see the inclusion of S_{12} in G.2. The reflections (a class of 3-transpositions) are the maps $S \longrightarrow S + [S,T]T$ where T is a 2-set or a 6-set, and [S,T] is the size of the intersection of S and T. (The 2-sets yield the transpositions of S_{12}.) There are 6 orbits of S_{12} on its conjugates, with intersections:

S_{12}, S_6 wreath M_2, S_4 wreath M_3, S_3 wreath M_4, S_2 wreath M_6, and M_{12},

where $M_2 = S_2$, $M_3 = S_3$, $M_4 = A_4$, $M_6 = PGL_2(5)$ and M_{12} is the Mathieu group (see M_{12}, "Shuffle").

"Presentation" G.2 ≅ <  | more relations > ; see page 232.

Remark : G is a maximal subgroup of the Fischer group Fi_{24}^{1}.

Order = 42,305,421,312,000 = $2^{18}.3^{6}.5^{3}.7.11.23$ Mult = 1 Out = 1

Constructions

Graph G : the automorphism group of a rank 3 graph of valence 891 on 2300 points in which the point stabilizer is $U_6(2).2$.

Leech G : the stabilizer of a type 2 vector V in the Leech lattice (see Co_1). Taking $V = (4,4,0^{22})$, $O = (0,0,0^{22})$, the 4600 points P with type(VP) = type(OP) = 2 fall naturally into 2300 pairs $\{P_L,P_R\}$ with $P_L + P_R - V = O$, namely $\{ (4,0,\pm4,0^{21}), (0,4,\mp4,0^{21}) \}$ (44), $\{ (3,1,\pm1^{22}), (1,3,\pm1^{22}) \}$ (1024), $\{ (2,2,\pm2^{6}0^{16}), (2,2,\mp2^{6}0^{16}) \}$ (1232). Two pairs $\{P_L,P_R\}$ $\{Q_L,Q_R\}$ are incident in the above graph just if type(P_iQ_j) is even.

Considering the Leech lattice modulo 2, the 2-spaces containing V become points in the quotient 23-dimensional representation over $\mathbb{F}_2$ (which contains an irreducible 22-dimensional representation). They are described below by the types of their non-zero vectors. In all cases except that marked * these vectors lift to real Leech lattice vectors of the appropriate types adding to O.

Sporadic Fischer group Fi_{22}

Order = 64,561,751,654,400 = $2^{17}.3^{9}.5^{2}.7.11.13$ Mult = 6 Out = 2

Constructions

Fischer G is generated by a conjugacy class of 3510 involutions, which are 3-transpositions; i.e. any non-commuting pair has product of order 3. Joining transpositions when they commute we obtain a rank 3 graph of valence 693, whose automorphism group is G.2. The centralizer of a transposition in G is $2^{\cdot}Fi_{21} \cong 2^{\cdot}U_6(2)$, and the centralizer of the product of two distinct transpositions is $2^2.2^8.U_4(2).2$ or $3 \times U_4(3).2$ according as they commute or not. Products of two or three mutually commuting transpositions are called bi- and tri-transpositions respectively. All maximal sets of mutually commuting transpositions (bases) are conjugate, and contain 22 transpositions, which generate an elementary Abelian group 2^{10} whose normalizer is a group $2^{10}:M_{22}$. There are three orbits of this group on transpositions: a transposition is either in the base, or commutes with a hexad of the base or with no transposition in the base. There are 22 basic, $2^5.77$ hexadic and 2^{10} anabasic transpositions. The centralizer of an anabasic transposition in $2^{10}M_{22}$ is a complementary M_{22}.

There are two classes of subgroups S_{10}, each having three orbits on transpositions, with stabilizers $2 \times S_8$, $2 \times (S_4 wr S_2)$, and $S_2 wr A_5$.

Modulo 2 3.G has a 27-dimensional unitary representation over $\mathbb{F}_4$, which exhibits it as a subgroup of $3.^2E_6(2)$. Explicit matrices have been computed.

Real G has a 78-dimensional real representation with basis $\{e_*, e_H\}$ where H ranges over the 77 hexads of S(3,6,22) (see M_{22}). It is generated by the 22 basic transpositions (i) which act as

$$e_* \to e_*, \quad e_H \to e_H \text{ (i in H)}, \quad e_H \to -e_H \text{ (i not in H)} \qquad \text{(each i)}$$

together with the anabasic transposition

$$S : 16e_* \to -5e_* + \sqrt{3}\Sigma e_H \qquad \text{(summed over all H)}$$

$$16e_H \to \sqrt{3}e_* - 7e_H - 3\Sigma e_K + \Sigma e_L \text{ (summed over K disjoint from H, and L meeting H in 2 points)}$$

The subgroup M_{22} fixes e_* and permutes the e_H. By enlarging this to $M_{22}:2$ we extend the representation to G.2.

Modulo 3 G.2 has a 77-dimensional representation modulo 3, obtained by reducing the above (written in terms of $\sqrt{3}e_*$, e_H) modulo 3, and factoring by the fixed vector $\sqrt{3}e_*$. The above formulae simplify to

$$i : e_H \to e_H \text{ (i in H)}, \quad e_H \to -e_H \text{ (i not in H)}$$

$$S : e_H \to \Sigma e_L - e_H \qquad \text{(summed over hexads L meeting H in 2 points)}$$

The 77-space is the space fixed by a transposition in the 253-dimensional representation of Fi_{23} (q.v.).

Presentation $G \cong \langle$ a b c d e f g | (abcdefh)^9=(bcdefgh)^9=(bcdefdhid)^{10}=1 $\rangle$; see page 232.

Constructions

Monster 5 x G : centralizer of a 5A-element in the Monster; the normalizer is $(D_{10} \times G).2$.

Real G has a 133-dimensional representation over $\mathbb{Q}(\sqrt{5})$, and the outer automorphism changes the sign of $\sqrt{5}$. The 133-space contains an orbit of 1140000 vectors which form a rank 12 graph of valence 462. The point stabilizer A_{12} has orbit lengths 1, 462, 2520, 2520, 10395, 16632, 30800, 69300, 166320, 166320, 311850, 362880. Orbits of equal length are fused in G.2. Explicit matrices have been computed.

$F_4(2)$

Chevalley group $F_4(2)$

Order = 3,311,126,603,366,400 = $2^{24}.3^6.5^2.7^2.13.17$ Mult = 2 Out = 2

Constructions

Chevalley G : the adjoint Chevalley group of type F_4 over the field $\mathbb{F}_2$; the automorphism group of the exceptional 27-dimensional Jordan algebra over $\mathbb{F}_2$.

Real 2.G has a 52-dimensional real representation, in which it permutes two orbits of 2 x 69888 special vectors. These two orbits are interchanged by the outer automorphism.

The typical vector can be written $(x_*;\ldots x_S\ldots)$ where S runs over the sets of size 1, 5 or 9 in a 10-set, and the 52-space is defined by the relations $x_{S'} = -x_S$ and $x_{S(1)}+\ldots+x_{S(10)} = 0$, where S' is the complement of S, and S(1), ..., S(10) have even pairwise intersections. The norm of v is $x_*^2/3 + \Sigma x_S^2/24$ (summed over one set S from each complementary pair). There is a subgroup $S_8(2)$ (containing S_{10}) whose transvections permute the sets S by the maps $S \longrightarrow S' + [S,T]T$ defined for each set T of size 2 or 6, where [S,T] is the parity of the intersection of S and T. (The sets of size 2 yield the transpositions of S_{10}). One orbit of special vectors can be defined in terms of a 5-set A. We say that S has type m_n if it meets A in m points, A' in n points. Then the special vectors are the $S_8(2)$-images of those with

$$x_* = x_U = 2,\ x_V = 0 \qquad \text{or} \qquad x_* = x_U = x_V = 1$$

where U ranges over sets of type 1_0, 5_4, 0_5 and 4_1, and U ranges over those of type 3_2.

The above special vectors generate a lattice L which is geometrically similar to its dual lattice L*. The quotient L*/L is an elementary Abelian group of order 2^{26} which can be identified with the trace zero portion of the Jordan algebra above. After rescaling, L* contains the particular special vectors with

$$x_* = 6,\ x_S = 0 \text{ (all S)} \qquad \text{or} \qquad x_* = 3,\ x_A = 9,\ x_T = 1$$

where A is a fixed set, and T ranges over all other sets meeting A oddly.

Remark : $2(2^2 \times G).2$ is the normalizer of a certain dihedral group of order 8 in the Monster group F_1.

Some maximal subgroups (including all local subgroups)

Sporadic Lyons group Ly

Order = 51,765,179,004,000,000 = $2^8.3^7.5^6.7.11.31.37.67$ Mult = 1 Out = 1

Constructions

Graphs G has been constructed as a group of permutations on 8835156 points, which can be regarded as the vertices of a rank 5 graph A. The point stabilizer in G is $G_2(5)$, which has orbit lengths 1, 19530, 968750, 2034375, 5812500. The corresponding 2-point stabilizers are $5^{1+4}:4S_4$, $U_3(3)$, $2(A_5xA_4).2$, and $(3xL_2(7)):2$ respectively.

There is also a permutation representation on 9606125 points forming a rank 5 graph B. The point stabilizer is $3^{\cdot}$McL:2, which has orbit lengths 1, 15400, 534600, 1871100, 7185024. The corresponding 2-point stabilizers are $3^{2+4}.4S_5$, $2S_7$, $4S_6$ and $5^{1+2}:S_3$ respectively.

The joint stabilizers of a point in each of the above graphs are $3^{\cdot}U_3(5):2$, $5^{1+2}:4S_3.2$, $U_3(3):2$ and $(2A_5 \times 3).2$.

Modulo 5 G has a 111-dimensional orthogonal representation over $\mathbb{F}_5$, on a space spanned by vectors $[\infty]$ and $[z,m,n]$, where $z = x + y\theta$ (x, y in $\mathbb{F}_5$, $\theta^2 = -3$) is the typical element of $\mathbb{F}_{25}$, and m, n are in $\{0,1,2,3,4,5,6,7,8,9,X,\bar{0},\bar{1},\bar{2},\bar{3},\bar{4},\bar{5},\bar{6},\bar{7},\bar{8},\bar{9},\bar{X}\}$. These vectors satisfy the relations

$$[z,m,n] = x[1,m,n] + y[\theta,m,n], \qquad [\bar{z},m,n] = [z,\bar{m},n] = [z,m,\bar{n}], \qquad [z,\bar{m},\bar{n}] = [z,m,n] = -[z,n,m]$$

where $\bar{z} = x - y\theta$. An orthogonal base consists of the 111 vectors $[\infty]$, $[1,a,b]$, $[\theta,a,b]$ ($b-a$ a quadratic residue modulo 11), of the respective norms 3, 1, 3.

G is generated by its subgroup $\langle A_m,B_P,C\rangle \cong 3^5:(M_{11} \times 2)$ together with the element D of order 3 inverted by C, where:

$$A_m : [\infty] \to [\infty], \quad [z,a,b] \to [w^{E(a,b,m)}z,a,b] \qquad (2w = -1 + \theta)$$

$$B_P : [\infty] \to [\infty], \quad [z,a,b] \to [z,P(a),P(b)]$$

$$C : [\infty] \to -[\infty], \quad [z,a,b] \to [\bar{z},a,b]$$

$$D : [\infty] \to [\infty] + \sum[wp_{mn},m,n]$$

$$[1,a,b] \to [\infty] + \sum[q_{mn}+\theta r_{mn},m,n]$$

$$[\theta,a,b] \to 3[\infty] + \sum[s_{mn}+\theta t_{mn},m,n]$$

whenever a,b,c,d,e,f,g,h,i,j,k is an arithmetic progression modulo 11 in which $b-a$ is a quadratic residue;

$E(a,b,m) = 0$ ($m = a,b$), 1 ($m = c,d,e,g,h,k$), 2 ($m = f,i,j$);

P is one of the monomial permutations (generating M_{11}):

(0123456789X), (13954)(267X8), $(0\bar{0})(1\bar{1})(3\bar{9}4\bar{5})(26X7)$;

the sums in the formulae for D are over the values below, and p_{mn} is the Legendre symbol $(m-n|11)$:

m =	a	b	c	d	e	f	g	h	i	j

Constructions

Real G has a 248-dimensional real representation, which when reduced modulo 3 exhibits it as a subgroup of $E_8(3)$. Explicit matrices have been constructed using the subgroup $2^5{\cdot}L_5(2)$ (the Dempwolff group).

Monster 3 x G : the centralizer of an element of class 3C in the Monster group F_1; the normalizer is S_3 x G.

Sporadic Fischer group Fi_{23}

Order = 4,089,470,473,293,004,800 = $2^{18}.3^{13}.5^2.7.11.13.17.23$ Mult = 1 Out = 1

Constructions

Fischer 2 x G : the centralizer of a transposition in Fi_{24}, the simple group G being the intersection with Fi_{24}'. For almost all purposes Fi_{23} is best regarded as a subgroup of Fi_{24} (q.v.). Thus, G is a 3-transposition group, generated by a conjugacy class of 31671 involutions, which form a rank 3 graph of valence 3510 when commuting transpositions are joined. The centralizer in G of a transposition is $2{\cdot}Fi_{22}$, and the centralizer of the product of two distinct transpositions is $2^2{\cdot}Fi_{21}.2 \cong 2^2{\cdot}U_6(2).2$ or 3 x $O_7(3)$ according as they do or do not commute. Products of 2 or 3 mutually commuting transpositions are called bi- or tri-transpositions respectively. All maximal sets of mutually commuting transpositions (bases) are conjugate and contain 23 transpositions, which generate an elementary Abelian group 2^{11} whose normalizer is a non-split extension $2^{11}{\cdot}M_{23}$. There are three orbits of $2^{11}{\cdot}M_{23}$ on transpositions: a transposition is either in the base, or commutes with a heptad or with a monad (singleton) of transpositions in the base. There are 23 basic transpositions, $2^5.253$ heptadic, and $2^{10}.23$ monadic.

There is a subgroup S_{12} which has four orbits on transpositions, with stabilizers 2 x S_{10}, S_4wrS_3, S_2wrA_6, and M_{12}.

Modulo 3 G has a 253-dimensional irreducible representation over $\mathbb{F}_3$. In the 783-dimensional 3-modular representation of Fi_{24} the 253-space is the space negated by a transposition. Coordinate vectors are the e_A for which [A] is an octad containing ∞.

Presentation See page 232.

Constructions

Leech 2.G : the automorphism group of the Leech lattice, the unique 24-dimensional even (i.e. all vector norms even) unimodular (i.e. determinant 1) lattice with no vector of norm 2. We construct this in terms of the Mathieu group M_{24} (q.v.) and the associated Golay code C. The lattice consists of all 24-dimensional vectors (x_i) over $\mathbb{Z}$ for which there is a Golay code word (c_i) and a number m = 0 or 1, such that

(i) all $x_i \equiv m \pmod 2$

(ii) $x_i \equiv m + 2c_i \pmod 4$

(iii) $\Sigma x_i \equiv 4m \pmod 8$

The unimodular norm is $\frac{1}{8}\Sigma x_i^2$, and the type of a vector is half this norm. There are 196560 = 2 x 98280 minimal vectors (norm 4, type 2):

1104 vectors	$(\pm 4^2 0^{22})$	(all possibilities)
97152 vectors	$(\pm 2^8 0^{16})$	(the support an octad of S(5,8,24), even signs)
98304 vectors	$(\mp 3 \pm 1^{23})$	(upper sign on a C-set, ∓ 3 anywhere)

The monomial group $2^{12}:M_{24}$ (becoming $2^{11}:M_{24}$ in G) is generated by the sign changes on C-sets, and permutations in M_{24}.

Orthogonal (2) Every vector of the Leech lattice is congruent modulo 2 to just one of:

the zero vector,

$\pm v$ (v of type 2),

$\pm v$ (v of type 3),

or $\{\pm v_1, \ldots \pm v_{24}\}$ (a coordinate frame of mutually orthogonal type 4 vectors).

The standard coordinate frame consists of the 48 vectors $(\pm 8, 0^{23})$.

G is the automorphism group of the 24-dimensional space over $\mathbb{F}_2$ equipped with the corresponding type function taking values 0, 2, 3, 4. The group is transitive on vectors of each type, and the type functon mod 2 is a quadratic form. There are 15 orbits of G on 2-dimensional subspaces (projective lines) which are described below by the types of their non-zero vectors. In all cases except those marked *, the non-zero vectors lift to real Leech lattice vectors of the appropriate types adding to zero. We give the pointwise stabilizers in Co_1.

244	$2^{1+8}A_8$	333	3^5M_{11}	333*	$U_3(5)$
334*	2 x M_{12}	334	2^4A_8	344	$L_3(4).S_3$
444	$2^{4+12}.3S_6$	444	$M_{12}.2$	444	$[2^{12}].L_3(2)$

Representatives of the three orbits of spaces of type 444 are generated by $(8,0^{23})$ together with $(4^4,0^{20})$, $(4,0^{11};2^{12-})$, or $(4^2,0^{14};2^8)$, respectively. Here and elsewhere k^{n+} (resp. k^{n-}) represents a set of n coordinates $\pm k$ with positive (resp. negative) product. The coordinates to one side of a semicolon form a C-set.

S-lattices Here is a method for classifying low-dimensional sublattices L of the Leech lattice. For any u in L there are Leech lattice vectors v and w such that u = v + 2w, with type(v) at most 4. If any such v has type 4, then we can choose coordinates so that $v = (8,0^{23})$, and then the pointwise stabilizer Stab(L) of L is contained in the monomial group $2^{12}:M_{24}$. Otherwise v is uniquely determined up to sign, and so Stab<L,w> has index at most 2 in Stab(L). By repeated adjunctions of such vectors w, we obtain a lattice L' such that either Stab(L') is in $2^{12}:M_{24}$ or L' is an S-lattice, i.e. for each u in L' the corresponding v and w are again in L', and v has type at most 3. An n-dimensional S-lattice which contains (up to sign) p type 2 vectors and q type 3 vectors has type 2^p3^q (with $p+q = 2^n-1$). The table describes the 12 orbits of S-lattices and their stabilizers in $2Co_1$. In every case the setwise stabilizer has the form Stab(L).Aut(L).

Dimension	Type	Stab(L)	Aut(L)	Dimension	Type	Stab(L)	Aut(L)
0	2^03^0	$2Co_1$	1	2	$333 = 2^03^3$	3^5M_{11}	2 x S_3
1	$2 = 2^13^0$	Co_2	2	3	2^53^2	$U_4(3)$	2 x D_8
1	$3 = 2^03^1$	Co_3	2	3	2^33^4	$U_3(5)$	2 x S_3
2	$222 = 2^33^0$	$U_6(2)$	2 x S_3	4	2^93^6	3^4A_6	2 x $(S_3xS_3).2$
2	$223 = 2^23^1$	M^cL	2^2	4	2^53^{10}	$5^{1+2}.4$	2 x S_5
2	$233 = 2^13^2$	HS	2^2	6	$2^{27}3^{36}$	$3^{1+4}.2$	2 x $U_4(2).2$

Vectors

The table below classifies vectors of type up to 16. If V is congruent modulo 2 to a vector of type 4 then the "shape" column gives the expression for V in the corresponding coordinate frame, and the stabilizing group is a subgroup of $2^{12}{:}M_{24}$. Otherwise the shape-symbol mu_a+nv_b (w_c) means that there are vectors u_a, v_b, w_c (of types a, b, c) satisfying $u_a+v_b+w_c=0$, with $V = mu_a+nv_b$, and the stabilizing group is the appropriate G_{abc} or $G_{abc}.2$ from the table to the right below. The numbers given provide a check on the group orders. The total number of vectors of type n is $65520(s_{11}(n)-t(n))/691$, where $s_{11}(n)$ is the sum of the 11th powers of the divisors of n, and t(n) is Ramanujan's tau function.

Type	Shape	Number/65520	Type	Shape	Number/65520		
2	v_2	3	13	u_3-2v_2 (w_4)	124 41600	abc	G_{abc}

Suzuki chain

The centralizer of an element of class 3D in Co_1 is $3 \times A_9$. The groups A_n (becoming $2A_n$ in $2Co_1$) obtained by fixing all but n points in this A_9 have normalizers

$NA_2 = Co_1$ $\quad NA_3 = 3.Suz.2$ $\quad NA_4 = (A_4 \times G_2(4)).2$ $\quad NA_5 = (A_5 \times J_2).2$

$NA_6 = (A_6 \times U_3(3)).2$ $\quad NA_7 = (A_7 \times L_2(7)).2$ $\quad NA_8 = A_8 \times S_4$ $\quad NA_9 = A_9 \times S_3$

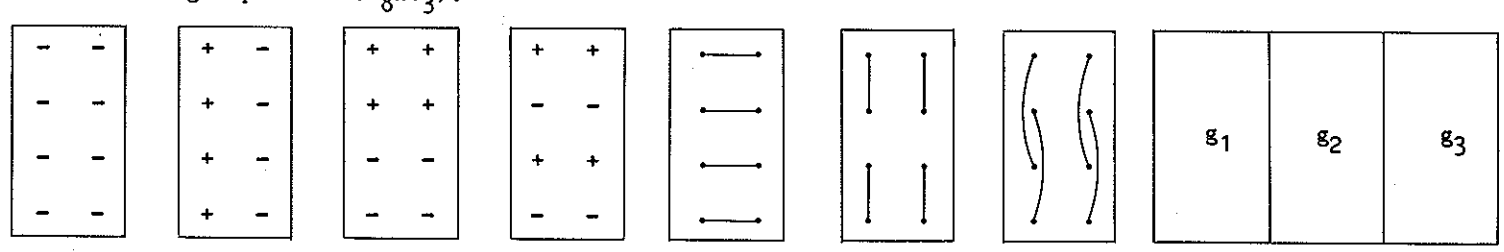
The cases n = 3,4,5 give rise to the complex and quaternionic constructions for the Leech lattice (see Suz, $G_2(4)$, J_2). Some other groups arise as normalizers of direct products of such groups A_n:

$NA_3^2 = 3^2U_4(3).2$, $\quad NA_4^2 = ((A_4 \times A_4).2 \times 2^4A_5).2$, (not maximal),

$NA_5^2 = ((A_5 \times A_5).2 \times D_{10}).2$, $\quad NA_3^3 = 3^{3+4}{:}2(S_4 \times S_4)$.

Code groups

Some subgroups arise in connection with "codes" whose "digits" may form a non-Abelian group. For example the seven elements at the left below generate a group 2_+^{1+6} acting on an 8-space, and the "codewords" (g_1,g_2,g_3) with $g_1g_2g_3 = \pm 1$ (acting on a 24-space as shown at the right) generate in $2Co_1 = 2.G$ a group 2^{3+12} whose normalizer is a maximal subgroup $2^{3+12}{\cdot}(A_8 \times S_3)$.

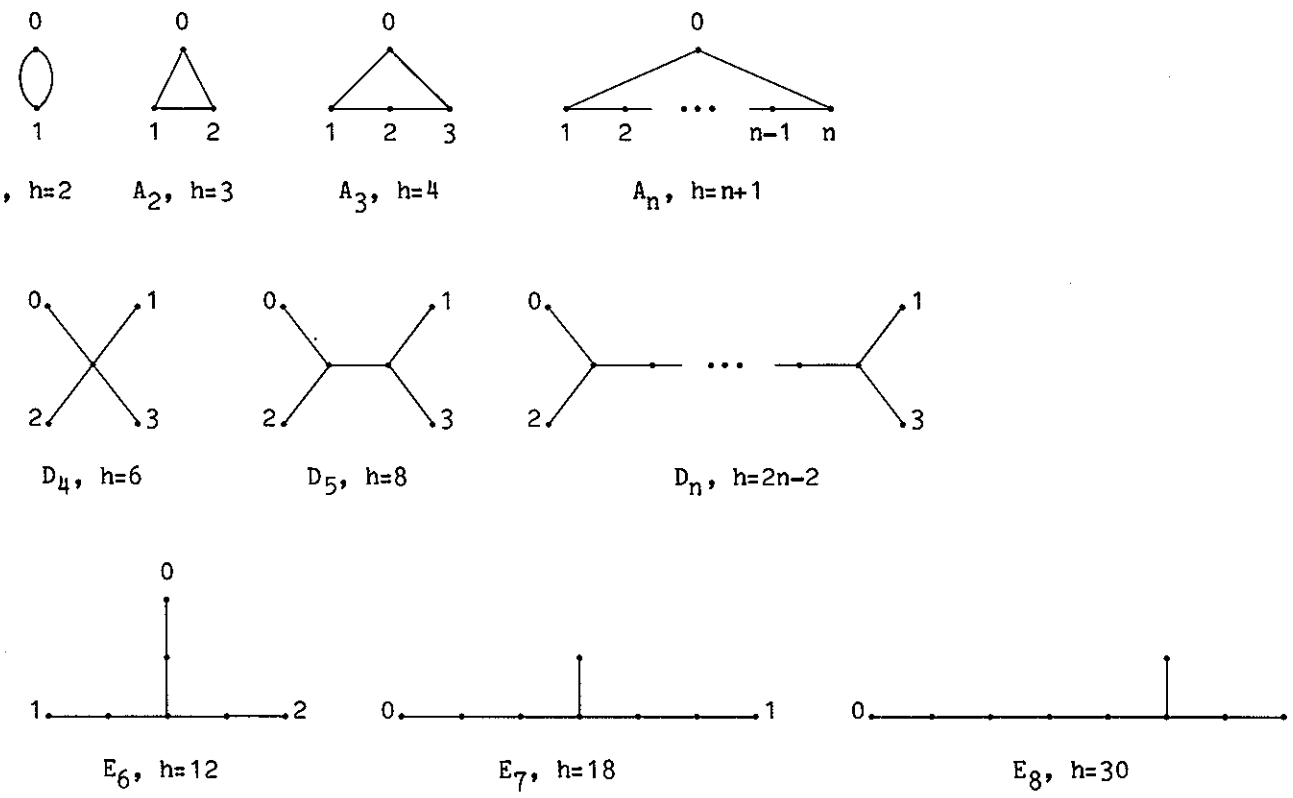


Similarly, the left and right multiplications by ±1, ±i, ±j, ±k define a group 2_+^{1+4} acting on the real 4-space of quaternions. Writing $i^0=1$, $i^1=1$, $i^w=j$, $i^{\bar{w}}=k$ we obtain from each word (abcdef) of the hexacode (see A_6) a word $(i^a,\ldots,i^f)$ of the quaternionic hexacode, and the left and right multiplications by such words (acting on the columns of the MOG, see $G_2(4)$) generate a group 2^{5+12} whose normalizer is a maximal subgroup $2^{5+12}{\cdot}(S_3 \times 3S_6)$ of $2Co_1$.

$Co_1 = F_{2-}$

Holes

The points of 24-space at maximal distance from the points of the lattice have a uniform description. The nearest lattice points to such a deep hole form a disjoint union of extended (affine) Dynkin diagrams (see below) when we join two points whose difference is a type 3 vector (and twice-join points whose difference is a type 4 vector). Each set of lattice points whose differences are at most type 4 and which forms an extended Dynkin diagram under these conventions can be found among the neighbours of a unique deep hole.



The 23 cases are just those with total subscript 24 and constant Coxeter number h. Each of the next nearest lattice points is joined (type 3 difference) to just one point in each component, which is a numbered point in the Figure above. The corresponding sequences of numbers form an additive group (the holy code) in which addition of digits is cyclic except for a component D_{2n+1}, for which it is a fourgroup. In the Code column of the table below, we use parentheses to indicate that the corresponding digits may be cyclically permuted.

Hole	Group	Code	Hole	Group	Code
D_{24}	(2)	1	$D_{16}E_8$	(2)	10
$E_8{}^3$	$(1).S_3$	000	A_{24}	(5).2	5
$D_{12}{}^2$	$(2^2).2$	(12)	$A_{17}E_7$	(6).2	31
$D_{10}E_7{}^2$	$(2^2).2$	110,301	$A_{15}D_9$	(8).2	21
$D_8{}^3$	$(2^3).S_3$	(122)	$A_{12}{}^2$	(13).4	15
$A_{11}D_7E_6$	(12).2	111	$E_6{}^4$	$(3^2).2.S_4$	1(012)
$A_9{}^2D_6$	$(5 \times 2^2).4$	240,501,053	$D_6{}^4$	$(2^4).S_4$	(012)3,1111
$A_8{}^3$	$(3^3).2.S_3$	(114)	$A_7{}^2D_5{}^2$	$(2^5).D_8$	1112,1721
$A_6{}^4$	$(7^2).2.A_4$	1(216)	$A_5{}^4D_4$	$(3^2.2^3).2S_4$	2(024)0,33001,30302,30033
$D_4{}^6$	$(2^6).3S_6$	111111,0(02332)	$A_4{}^6$	$(5^3).2.S_5$	1(01441)
$A_3{}^8$	$(2^8).2.2^3L_2(7)$	3(2001011)	$A_2{}^{12}$	$(3^6).2M_{12}$	2(11211122212)
$A_1{}^{24}$	$(2^{12}).M_{24}$	1(000001010011001101011 11)			

The portion of the group inside the initial parenthesis is the additive group of the code. In each case, the nearest and next-nearest neighbours to the hole suffice to determine the lattice.

The vertices of a hole of type D_{24} can be taken, using the shuffle numbering for M_{24}, to be the vectors

$(-3,1^{23})$, with the -3 on one of $0^-,1^-,\ldots,11^-,11^+$,

$(5,1^{23})$, with the 5 on 0^+,

$(2^8,0^{16})$, 2s on one of the 11 octads found under M_{24}, section "Mathieu 12"

The two next nearest points are (0^{24}) and $(0^{12},2^{12})$, with the 2s on the dodecad $0^+,1^+,\ldots,11^+$. The corresponding Leech roots (see "hyperbolic", below) are

$(0^n,1,-1,0^{23-n}|0)$ $(n = 0,\ldots,22)$, $(-1,-1,0^{23}|0)$, $(0^{22},1,1,1|1)$, and $(0^{23},1,-1|0)$, $(-\frac{1}{2},\frac{1}{2}^{23}\frac{3}{2}|\frac{5}{2})$.

$F_2 = Co_1$

Hyperbolic

The Lorentzian lattice $II_{25,1}$ consists of the vectors $(x_0,\ldots,x_{24}|t)$ in which the coordinates are either all in $\mathbb{Z}$ or all in $\mathbb{Z}+\frac{1}{2}$, and have $\Sigma x_i + t$ in $2\mathbb{Z}$, in a space equipped with the Lorentzian norm $\Sigma x_i^2 - t^2$. A vector r of the lattice is called a Leech root if it satisfies $r.r = 2$, $r.w = -1$, where w is the particular norm 0 vector $(0,1,2,\ldots,24|70)$. Under the metric defined by $d(r,s)^2 = \mathrm{Norm}(r-s)$, the Leech roots form a (non-linear) set isometric to the Leech lattice. The reflection subgroup of $\mathrm{Aut}(II_{25,1})$ is generated by the reflections in the Leech roots, and the full group is an extension of this by the negative of the identity operation and the (infinite) affine automorphism group $\mathbb{Z}^{24}{:}2Co_1$ of the Leech lattice.

Order = 86,775,571,046,077,562,880 = $2^{21}.3^3.5.7.11^3.23.29.31.37.43$ Mult = 1 Out = 1

Constructions

Modulo 2 G has a 112-dimensional irreducible representation over $\mathbb{F}_2$, in which there is an orbit of 173,067,389 special vectors, each fixed by a group $2^{11}:M_{24}$. Explicit matrices have been computed.

The group can be defined as the stabilizer of a certain 4995-dimensional subspace of the exterior square of this representation, and two vectors in the 112-space are called neighbours if their exterior product lies in this 4995-space. The neighbourhood of a special vector is a 12-space, and consists of the zero vector, the special vector, 2x759 octad vectors whose neighbourhood is 6-dimensional, and 2x1288 dodecad vectors whose neighbourhood is 2-dimensional. The stabilizer of an octad vector is $2^{10}:L_5(2)$. There are also pentads of special vectors, stabilized by $2^{3+12}.(S_5 x L_3(2)) \cong (2^{3+12}:S_5):L_3(2) \cong (2^{3+12}:L_3(2)):S_5$. The 112-space reduces under the four large maximal subgroups as follows:

$2^{11}:M_{24}$	1.11.44.44.11.1 (uniserial)
$2^{10}:L_5(2)$	$(1 \oplus 5).10.40.40.10.(1 \oplus 5)$
$2^{1+12}.3M_{22}.2$	$10.30.(10.10 \oplus 12).30.10$
$2^{3+12}.(S_5 x L_3(2))$	$4.12.(3.3.3.3 \oplus 12).32.(3.3.3.3 \oplus 12).12.4$

Twisted group $^2E_6(2)$

Order = 76,532,479,683,774,853,939,200 = $2^{36}.3^9.5^2.7^2.11.13.17.19$ Mult = $2^2 \times 3$ Out = S_3

Constructions

Steinberg G : the centralizer in $E_6(4)$ of an outer automorphism of order 2.

3.G.3 has a 27-dimensional representation over $\mathbb{F}_4$, which remains irreducible on restriction to $3{\cdot}Fi_{22}$. There is a cubic form which is invariant up to scalar multiplication.

Remark : 2.G.2 is the involution centralizer in the Baby Monster; $2^2.G.S_3$ is the normalizer of a certain 4-group in the Monster. For a possible presentation, see page 232.

Sporadic Fischer group Fi'_{24}

Order = 1,255,205,709,190,661,721,292,800 = $2^{21}.3^{16}.5^{2}.7^{3}.11.13.17.23.29$ Mult = 3 Out = 2

Constructions

Fischer G.2 is generated by a conjugacy class of 306936 involutions, which are 3-transpositions, i.e. any non-commuting pair has product of order 3. Joining transpositions when they commute we obtain a rank 3 graph of valence 31671, whose automorphism group is again G.2. The centralizer of a transposition is 2 x Fi_{23}, and the centralizer of the product of two distinct transpositions is $2^2Fi_{22}.2 \equiv (2 \times 2{\cdot}Fi_{22}){:}2$ or $3 \times O^{+}_{8}(3){:}S_3$ according as they commute or not. Products of 2, 3, or 4 mutually commuting transpositions are called bi-, tri- or tetra-transpositions respectively. All maximal sets of mutually commuting transpositions (bases) are conjugate and contain 24 transpositions, which generate an elementary Abelian group 2^{12} whose normalizer is a non-split extension $2^{12}{\cdot}M_{24}$. The sets of transpositions in a base whose product is 1 are the C-sets of a binary Golay code (see M_{24}), and so the elementary Abelian 2^{12}-group has the structure of the Golay cocode. There are three orbits of $2^{12}M_{24}$ on transpositions: a transposition is either in the base, or commutes with an octad or with a duad of transpositions in the base. There are 24 basic transpositions, $2^5.759$ octadic, and $2^{10}.276$ duadic. Any 8 mutually commuting transpositions with trivial product (forming an octad) lie in just three bases B_1, B_2 and B_3. With respect to B_1 the remaining 32 elements of B_2 and B_3 are the octadic transpositions for the corresponding octad.

"Orthogonal" G has a subgroup $H \equiv O^{-}_{10}(2)$ which has three orbits on transpositions:

(i) the 528 reflections of H

(ii) 104448 transpositions centralized by A_{12} in H

(iii) 201960 transpositions centralized by $2^{6+8}(A_7 \times 3)$ in H

The transpositions of the third orbit fall naturally into octads, and the stabilizer $2^{6+8}(A_8 \times 3)$ of such an octad has index 2 in its stabilizer in G. An explicit form for the graph, and the action of a generating set of transpositions, have been found using the orbit decomposition under the subgroup S_{12} of H.2.

Complex 3.G has a 783-dimensional complex representation over $\mathbb{Q}(w)$, where $w = z3$. The 783 coordinate 1-spaces are indexed by the points i of a 24-set [U] and the octads of a Steiner system S(5,8,24) on [U] (see M_{24}). There is an invariant algebra with multiplication $x * y$, antilinear in each variable, and 3.G.2 is generated by the antilinear maps ("reflections") $x \longrightarrow x^r = x * r - \langle r,x\rangle r$, for 3 x 306936 root vectors r. These are the scalar multiples, by powers of w, of certain vectors:

$(-7,1^{23}|0^{759})$ (3x24) (basic)

$\frac{1}{2}(-1^8,1^{16}|\pm\theta^1,0^{280},0^{448},\pm1^{30})$ $(3\times2^5.759)$ (octadic)

$\frac{1}{8}(-7^2,1^{22}|\pm\theta^{77},0^{352},\pm1^{330})$ $(3\times2^{10}.276)$ (duadic)

where the inner product $\langle x,y\rangle$ of vectors $x = (\ldots x_i\ldots|\ldots x_A\ldots)$ and $y = (\ldots y_i\ldots|\ldots y_A\ldots)$ is $\frac{1}{8}\Sigma x_i\bar{y}_i + \Sigma x_A\bar{y}_A$. The reflection in $(-7,1^{23}|0^{759})$ (with the -7 in the i'th coordinate) negates the coordinates corresponding to octads containing i, in addition to complex conjugating all coordinates. For more details see the next section.

Loop The sign problem in the above construction is rather subtle, and is best understood as follows. There is a loop P of order 2^{13}, which has a homomorphism $A \longrightarrow [A]$ (with kernel $\{\pm1\}$) onto the additive group of the binary Golay code. The loop is defined up to isomorphism by the equations

$$A^2 = (-1)^{\frac{1}{4}|[A]|}$$

$$BA = (-1)^{\frac{1}{2}|[A]\cap[B]|}AB$$

$$A(BC) = (-1)^{|[A]\cap[B]\cap[C]|}(AB)C$$

and satisfies the Moufang identity $A((BC)A) = (AB)(CA)$. If $A_1, \ldots, A_{12}$ are elements of P such that $[A_1], \ldots, [A_{12}]$ generate the C-sets, then there are 2^{12} standard automorphisms S to each permutation [S] of M_{24}, such that $[A_1^S], \ldots, [A_{12}^S]$ are the images under [S] of $[A_1], \ldots, [A_{12}]$. The standard automorphisms form the group $2^{12}{\cdot}M_{24}$ and are called even or odd according as $U^S = U$ or $-U$, where U is a particular one of the two loop elements mapping to the universal C-set [U]. The standard automorphisms corresponding to the identity element of M_{24} are named by C^*-sets d and take A to A or -A according as d meets [A] evenly or oddly.

There are 24 coordinate vectors e_i (i in [U]) of norm $\frac{1}{8}$, and 2 x 759 coordinate vectors e_A of norm 1 which are indexed by the loop elements A for which [A] is an octad, and satisfy $e_{-A} = -e_A$. We can now define the 32 octadic root vectors corresponding to a given octad a as follows: There are 32 C-sets {}, $b_1,\ldots,b_{30}$, a' disjoint from a, where $b_1,\ldots,b_{30}$ are octads and a' is the complement of a. Their inverse images in P form an elementary Abelian group of order 2^6. There are therefore 32 ways to select pre-images 1, $B_1,\ldots,B_{30}$, UA forming a group. Each such way determines the signs in one of the octadic root vectors $v = \frac{1}{2}(-1^8,1^{16}|\pm\theta^1,0^{280},0^{448},\pm1^{30})$ corresponding to the octad a by:

$$2v = \Sigma e_j - \Sigma e_i + \theta e_A + \Sigma B_b \text{ (summed over i in [A], j not in [A]).}$$

If two octads a_1, a_2 meet in a duad d then the typical duadic root vector for d has the form r^s where r and s are octadic root vectors for a_1 and a_2.

$F_{3+} = Fi'_{24}$

Algebra — The algebra is antilinear in each variable, so should properly be regarded as defined on the 2x783-dimensional real form of the representation. In terms of the "reflection" $x \to x^r$ in a root vector r, we have $x * r = x^r + \langle r,x\rangle r$. We define $E_i = 8e_i$, so that $\{\ldots,E_i,\ldots,e_A,\ldots\}$ is the dual base to $\{\ldots,e_i,\ldots,e_A,\ldots\}$. Then the non-zero products of basis elements are

$$2E_i*E_i = -81e_i+15\Sigma e_j,\quad 2E_i*E_j = 15e_i+15e_j-\Sigma e_k \ (j \neq i)\ (k \neq i,j)$$

$$2E_i*e_A = 2e_A*E_i = 3e_A,\quad 2E_j*e_A = 2e_A*E_j = -e_A,\quad 2e_A*e_A = -2e_A*e_{-A} = 3\Sigma e_i - \Sigma e_j \ (i \text{ in } A,\ j \text{ not in } A)$$

$$2e_A*e_B = e_{AB} \text{ or } \theta e_{ABU} \text{ if } [AB] \text{ or } [ABU] \text{ is an octad.}$$

Modulo 3 — G.2 has a 783-dimensional representation over $\mathbb{F}_3$ obtained from the above by reducing modulo θ. This has a fixed vector $I = \Sigma e_i$ (i in [U]), and on the 782-space modulo I there is an invariant algebra (obtained from the negative of the above algebra) for which the only non-zero products of basis vectors are

$$e_i*e_j = e_i+e_j \ (i \neq j) \qquad e_j*e_A = e_A*e_j = e_A \ (j \text{ not in } [A])$$

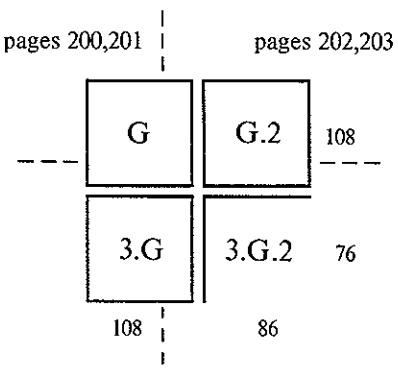
$$e_A*e_A = -e_A*e_{-A} = \Sigma e_i \ (i \text{ in } [A]) \qquad e_A*e_B = e_{AB} \ ([AB] \text{ an octad})$$

G acts irreducibly on the 781-dimensional space orthogonal to I.

"Presentation" 3.G.2 ≅ < ——————————— | more relations > ;

omitting the lowest node leaves $O^-_{10}(2).2$; omitting the lowest pair of nodes leaves S_{12}.

The leftmost and rightmost nodes are redundant. By adjoining more redundant nodes the diagram may be enlarged to the incidence graph of the 9 points and 9 lines of the Pappus configuration. See page 232.



Some maximal subgroups (including all p-local subgroups for p ≠ 2)

Constructions

Transposition G is generated by a conjugacy class (2A) of involutions, which are (3,4)-transpositions; that is, any non-commuting pair has product of order 3 or 4. G has been explicitly constructed as a permutation group on its 13571955000 transpositions t, which fall into orbits of sizes 1, 3968055, 23113728, 2370830336, and 11174042880 under the stabilizer $2\cdot({}^2E_6(2)).2$ of a particular transposition t_0. These orbits correspond to the conjugacy classes 1A, 2B, 2C, 3A and 4B for t_0t.

Monster 2.G is the centralizer of an involution of class 2A in the Monster group M, and is the stabilizer in M of the corresponding transposition vector (see M, section "Vectors"). The irreducible 196883-dimensional representation of M restricts to 2.G as the sum of irreducible representations of degrees 1, 4371, 96255, 96256. The first three of these yield irreducible representations of G, since the central involution acts trivially.

"Presentation" G ≅ < | more relations >

(The leftmost node is redundant. See page 232.)

Chevalley group $E_7(2)$

Order = 7,997,476,042,075,799,759,100,487,262,680,802,918,400

$= 2^{63}.3^{11}.5^{2}.7^{3}.11.13.17.19.31.43.73.127$

Mult = 1 Out = 1

Constructions

Chevalley G : adjoint Chevalley group of type E_7 over the field $\mathbb{F}_2$; G has a 56-dimensional representation over $\mathbb{F}_2$ which supports a non-trivial quartic invariant.

Maximal 2-local subgroups

$[2^{33}]:O^+_{12}(2)$

$[2^{47}]:(S_3 x L_6(2))$

$[2^{53}]:(S_3 x L_3(2) x A_8)$

$[2^{50}]:(L_3(2) x L_5(2))$

$[2^{42}]:(S_3 x O^+_{10}(2))$

$[2^{27}]:E_6(2)$

$[2^{42}]:L_7(2)$

Some other subgroups

$L_8(2):2$

$U_8(2):2$

$E_6(2):2$

$3^{\cdot}(^2E_6(2)):S_3$

$S_3 \times O^+_{12}(2)$

$(L_3(2) \times L

Constructions

Griess G : the group of orthogonal automorphisms of a certain 196884-dimensional algebra. There is a fixed vector I, and G acts irreducibly on the 196883-space orthogonal to I. A base for the space can be defined in terms of the action of the maximal subgroup $2^{1+24}Co_1$. The algebra and an element of G outside this subgroup have been computed explicitly in this base. The multiplication used below differs slightly from that of Griess, so care is necessary in comparing results.

Algebra The inner product (a,b) and algebra product a * b defined later have the following properties:

a * b = b * a , and (a,b) is positive definite;

(a * b , c) = (a , b * c) = (a,b,c), say;

if (a * a) * c = a * (a * c), then (a * b) * c = a * (b * c) for all b (and we say that a and c alternate);

(a * a , c * c) $\geq$ (a * c , a * c) , with equality just when a and c alternate.

If a set S is closed under taking algebra squares s * s , then its annihilator { x | x * s = 0 for all s in S } and alternator { x | x alternates with all s in S } are subalgebras. If elements v_1, v_2, ... all alternate with their own squares and with each other, then the subalgebra they generate is associative.

The algebra has a unit 1, and the projection 1_S of 1 onto any subalgebra S is a unit for S. For an idempotent i, the eigenvalues of the map $x \longrightarrow x * i$ lie in [0,1], and the 0- and 1-eigenspaces $V_0(i)$ and $V_1(i)$ are subalgebras with $V_0(i) * V_1(i) = 0$. Moreover, if i and j are idempotents with (i,j) = 0, then $V_1(i) * V_1(j) = 0$.

To each element of class 2A there is a corresponding transposition vector t with t * t = 64t, and there is a lattice containing 1 and these vectors that is closed under algebra multiplication. When equipped with the inner product 2(a,b) this lattice is integral (and probably unimodular). For further details see the section "Vectors" below.

In the following sections, we shall describe a simplified construction for G and the algebra using the loop P described under Fi_{24}', section "Loop". The several sections construct:

The group N, which is a 4-fold cover of the normalizer N_0 of a certain four-group {1,x,y,z} in the Monster.

The Leech link, which is a homomorphism from a certain group Q_x onto the Leech lattice modulo 2.

Representations of various groups, which can be assembled into representations of degree 196884 for N_x, N_y, N_z, the centralizers of x, y, z in N.

A dictionary which identifies the 196884-spaces for N_x, N_y, N_z compatibly with the action of their intersection N_{xyz}.

A multiplication on the resulting 196884-space, invariant under G.

Enlargements of certain quotients N_{x0}, N_{y0}, N_{z0} of N_x, N_y, N_z to groups G_{x0}, G_{y0}, G_{z0} which preserve the algebra and generate the Monster, in which they are the centralizers of x, y, z.

Vectors corresponding to various elements of G. The action of a transposition can be defined in terms of the corresponding vector and the algebra structure.

The group N This is defined using the loop P described under Fi_{24}', section "Loop". It is the group of permutations of the triples (A,B,C) of loop elements with ABC = 1 generated by the particular maps (specified by the image of (A,B,C)):

x_D : $(\bar{D}A\bar{D}, DB, CD)$ y_D : $(AD, \bar{D}B\bar{D}, DC)$ z_D : $(DA, BD, \bar{D}C\bar{D})$ (D in P)

$x_S = y_S = z_S$: (A^S, B^S, C^S) ($U^S = U$, i.e. S even)

x_S : $(\bar{A}^S, \bar{C}^S, \bar{B}^S)$ y_S : $(\bar{C}^S, \bar{B}^S, \bar{A}^S)$ z_S : $(\bar{B}^S, \bar{A}^S, \bar{C}^S)$ ($U^S = -U$, i.e. S odd)

where S is a standard automorphism of P and $\bar{A} = A^{-1}$ is the loop inverse of A. Important particular cases of x_S, y_S, z_S are x_d, y_d, z_d for d a C^*-set. The composition factors in the structure $(2^2x2^2).2^{11}.2^{22}.(S_3xM_{24})$ are defined modulo earlier ones by

2^2 : $K = \{ 1, k_1=y_Uz_{-U}, k_2=z_Ux_{-U}, k_3=x_Uy_{-U} \}$.

2^2 : $V = \{ 1, x=x_{-1}, y=y_{-1}, z=z_{-1} \}$

2^{11} : $\langle x_d \mid$ d an even C^*-set $\rangle$

2^{22} : $\langle x_D, y_D, z_D \mid$ D in P $\rangle$, in which we have $x_Dy_Dz_D=1$

S_3 : $\langle x_i, y_i, z_i \rangle$ for some i in [U], regarded as an (odd) C^*-set

M_{24} : $\langle x_S$ or y_S or $z_S \mid$ all S $\rangle$, in which x_S, y_S, z_S all act as [S], the permutation corresponding to S.

By considering the subgroups S_2 and S_1 in S_3, we see that N has subgroups N_x, N_y, N_z of index 3 whose intersection N_{xyz} has index 6 in N. The group $N_x = (2^2x2^2).2^{11}.2^{22}.(S_2xM_{24})$ has the alternative structure $2.2^{1+24}.(2^{12}:M_{24})$ in which the normal subgroup 2.2^{1+24} is called Q_x and is generated by the x_D and x_d, while the quotient N_x/Q_x is isomorphic to the group of monomial automorphisms of the Leech lattice, and is generated by y_D (or z_D), acting as the sign-change on [D], and x_S, acting as the permutation [S].

The Leech link The typical element $x_A x_B x_C \ldots$ of Q_x is written $x_{A.B.C.\ldots}$, and we write $x_{-R} = x_{-1.R}$. The formula $x_D x_E = z^{\frac{1}{2}|d|} x_{DE} x_d$, where d is the intersection of [D] and [E], regarded as a C^*-set, shows that Q_x contains z, and so contains $k_1 = x_U z$. There is a natural homomorphism taking $x_R \to v_R$, from Q_x onto the Leech lattice modulo 2, defined by

$$x_D \to (2_{\text{on } [D]}, 0_{\text{elsewhere}}) \qquad x_i \to (-3_{\text{on } i}, 1_{\text{elsewhere}})$$

where i is one of the 24 points of [U], regarded as a C^*-set. The preimages of the 98280 type 2 vectors of the Leech lattice (modulo 2) are called the <u>short elements</u> of Q_x. We use x_R^+ and x_R^- to mean $x_{U.R}$ and $x_{-U.R}$ when these are short, and otherwise x_R. Then typical short elements, and their images in the Leech lattice, are

$$x_{\pm ij} \to (4_{\text{on } i}, -4_{\text{on } j}, 0_{\text{elsewhere}})$$
$$x^+_{\pm ij} \to (4_{\text{on } i,j}, 0_{\text{elsewhere}})$$
$$x^+_{D.i} \to (-3_{\text{on } i}, 1_{\text{elsewhere}}) \text{ sign-changed on } [D]$$
$$x^+_{D.d} \to (2_{\text{on } [D]}, 0_{\text{elsewhere}}) \text{ sign-changed on } d$$

where in the last line [D] is an octad and d an even subset of it.

Representations The group N_x has the following representations (named by their degrees subscripted by x):

24_x : kernel $\langle x_D, x_d \rangle$ of order 2^{26}, image $2^{12}{:}M_{24}$.

This acts on the space generated by 24 orthogonal vectors i_1 (i in [U]) of norm $\frac{1}{8}$. The image is the group of monomial automorphisms of a copy of the Leech lattice L (with $(\ldots, x_i, \ldots)$ interpreted as $\Sigma x_i i_1$) in which y_D and z_D act as the sign-change on [D], and x_S as the permutation [S] in M_{24} that corresponds to S.

4096_x : kernel $\langle y_U, z_{-U} \rangle$ of order 2^2, image $2^{1+24}.(2^{11}{:}M_{24})$.

This is contained in the matrix normalizer of the faithful representation of the extraspecial group 2^{1+24}. There are 2 x 4096 norm 1 basis vectors D_1^- and D_1^+, permuted like the triples (?,D,?) and (?,?,D) under conjugation (? indicates an immaterial entry) with the identifications $(-UD)_1^- = D_1^-$, $(UD)_1^+ = D_1^+$, $(-D)_1^\pm = -(D_1^\pm)$.

98280_x : kernel $\langle k_1, k_2, k_3, x \rangle$ of order 2^3.

This is a monomial representation on norm 1 vectors X_R with $X_R = -X_R$ permuted in the way that the short elements x_R of Q_x are permuted under conjugation by the quotient group $N_{x1} = N_x/\langle k_1 \rangle$ of N_x.

300_x : the symmetric tensor square of 24_x.

This acts on symmetric 24 x 24 matrices A. As basis elements, we take the matrices $(ij)_1$ (for $i \neq j$) and $(ii)_1$, whose only non-zero entries are 1 in places (i,j) and (j,i) (for $(ij)_1$) and (i,i) (for $(ii)_1$). In tensor notation we have $(ij)_1 = i_1 \otimes j_1 + j_1 \otimes i_1$ and $(ii)_1 = i_1 \otimes i_1$.

98304_x : the tensor product of 4096_x and 24_x. We take the basis elements $D_1^\pm \otimes i_1$ to have norm 1.

Dictionary We define $196884_x = 300_x + 98280_x + 98304_x$. Since K is in the kernel, this can be regarded as a representation of $N_{x0} = N_x/K$. We define similar representations 196884_y of N_y or N_{y0} and 196884_z of N_z or N_{z0} by cyclically permuting the letters (x,y,z), (X,Y,Z), (A,B,C), and the subscripts (1,2,3) in all our notations. Thus there is a representation 300_y of N_y with basis elements $(ij)_2$ and $(ii)_2$, and typical element B. The dictionary reads:

(A,X,1)-name		(B,Y,2)-name		(C,Z,3)-name	
$(ij)_1$	=	$Y_{ij} + Y^+_{ij}$	=	$Z_{ij} - Z^+_{ij}$	
$X_{ij} - X^+_{ij}$	=	$(ij)_2$	=	$Z_{ij} + Z^+_{ij}$	
$X_{ij} + X^+_{ij}$	=	$Y_{ij} - Y^+_{ij}$	=	$(ij)_3$	
$(ii)_1$	=	$(ii)_2$	=	$(ii)_3$	= (ii), say
$X_{D.i}$	=	$D_2^+ \otimes i_2$	=	$D_3^- \otimes i_3$	
$D_1^- \otimes i_1$	=	$Y_{D.i}$	=	$D_3^+ \otimes i_3$	
$D_1^+ \otimes i_1$	=	$D_2^- \otimes i_2$	=	$Z_{D.i}$	
$X^+_{D.d}$	=	$\frac{1}{8}\Sigma -_e -_d e Y^+_{D.e}$	=	$\frac{1}{8}\Sigma -_d -_d e Z^+_{D.e}$	
$\frac{1}{8}\Sigma -_d -_d e X^+_{D.e}$	=	$Y^+_{D.d}$	=	$\frac{1}{8}\Sigma -_e -_d e Z^+_{D.e}$	
$\frac{1}{8}\Sigma -_e -_d e X^+_{D.e}$	=	$\frac{1}{8}\Sigma -_d -_d e Y^+_{D.e}$	=	$Z^+_{D.d}$	

The sums in the last three rows are over all C^*-sets e which can be represented by even subsets of [D], and the symbol $-_d$ means $(-1)^{\frac{1}{2}|d|}$. In the three previous rows it is supposed that i is not in [D].

Multiplication There is a symmetric invariant multiplication * defined on 196884-space. We specify it below in the notation of 196884_x.

$$A * A' = 2(AA' + A'A)$$
$$X_R * A = A * X_R = (A, v_R \otimes v_R).X_R$$
$$X_R * X_S = \begin{cases} \pm v_R \otimes v_R & (X_{R.S} = X_{\pm 1}) \\ X_{R.S} & (X_{R.S} \text{ short}) \\ 0 & (\text{otherwise}) \end{cases}$$
$$A * (W \otimes v) = (W \otimes v) * A = W \otimes vA + \frac{1}{8} \operatorname{tr} A \,.\, W \otimes v$$
$$X_R * (W \otimes v) = (W \otimes v) * X_R = \frac{1}{8} W^R \otimes [v - 2(v, v_R).v_R]$$
$$(W \otimes v) * (W' \otimes v') = \Sigma \tfrac{1}{2}(W^R, W')[(v,v') - 2(v,v_R)(v',v_R)].X_R + (W,W').[(v,v')I + 4.v \otimes v' + 4.v' \otimes v]$$

Vectors of 300_x are represented by 24 x 24 symmetric matrices A, A', ... The general vector of 24_x is called v, and v_R denotes either of the two type 2 Leech lattice vectors corresponding to the short element x_R of Q_x. W is the typical vector in 4096_x-space. Its image under x_R is written W^R. The sum in the last line is over all short X_R (the factor $\frac{1}{2}$ may be omitted if we sum instead over just one of each pair X_R, X_{-R}). The quadratic form on 196884-space is defined by the condition that $(ij)_1$ has norm 2, and all our other basis vectors have norm 1. Our basis vectors are orthogonal except when opposite or equal.

$M = F_1$

Enlargements The images of N_x in the representations 24_x and 4096_x are matrix groups $N_x(24) = 2^{12}{:}M_{24}$ and $N_x(4096) = 2^{1+24}.(2^{11}{:}M_{24})$ which have a common quotient $2^{11}{:}M_{24}$, and can be extended to matrix groups $G_x(24) = 2{\cdot}Co_1$ and $G_x(4096) = 2^{1+24}.Co_1$ having a common quotient Co_1 (extending $2^{11}{:}M_{24}$). Since the intersection of the kernels of N_x for 24_x and 4096_x is $K_1 = \langle k_1 \rangle$, it follows that $N_{x1} = N_x/K_1$ is isomorphic to the diagonal product $N_x(24) \Delta_{2^{11}:M_{24}} N_x(4096)$ which can be extended to a larger group $G_{x1} = G_x(24) \Delta_{Co_1} G_x(4096)$ of structure $2^{1+24}.2Co_1$. (The diagonal product $A \Delta_C B$ is the set of (a,b) in the Cartesian product whose coordinates have the same image in C.) Plainly the representations 24_x and 4096_x extend to G_{x1}, as does 98280_x since $Q_{x1} = Q_x/K_1$ is still normal and G_{x1} still permutes the short elements of Q_{x1} by conjugation. So the representation 196884_x extends to G_{x1}. Since k_2 and k_3 are represented trivially, the result is actually a representation of $G_{x0} = G_{x1}/K_2$, where $K_2 = \langle k_2 \rangle$. The three such groups G_{x0}, G_{y0}, G_{z0} which can be supposed (using the dictionary) to act on a single 196884-space, generate the Monster group G.

Vectors There are certain vectors in the algebra that are permuted by G in the way that it transforms the elements of certain conjugacy classes. Thus the entire group fixes the unit 24x24 matrix I, regarded as a vector of 300_x, 300_y or 300_z, which satisfies $(I,I) = 24$, $I * x = 4x$, and so $\frac{1}{4}I$ is a unit element 1 for the algebra, corresponding to the unit element of G. Again, the centralizer (a double cover of the Baby Monster) of an element of class 2A (a <u>transposition</u>) fixes a further vector t (which we call a <u>transposition vector</u>) satisfying $(t,t) = 128$, $t * t = 64t$. The lattice generated by 1, t, $t * t'$, where t and t' range over all transposition vectors, is closed under algebra multiplication, and integral (and probably unimodular) with respect to the inner product $2(a,b)$.

There are similar vectors corresponding to (written $\longleftrightarrow$) elements of certain other conjugacy classes. We describe the structure of the algebra generated by transposition vectors t_0 and t_1 corresponding to two transpositions a and b. The conjugacy classes of ab and its powers are given in the table, followed by certain relations in the algebra. These involve the vectors t_n corresponding to transpositions $a(ab)^n$, and t, u, v, $\pm w$ corresponding to any powers of ab that lie in the respective conjugacy classes 2A, 3A, 4A, 5A.

1A	$t_0 * t_0 = 64t_0$, $(t_0,t_0) = 128$, $(t_0,1) = 2$, $(1,1) = 3/2$
2A, 1A	$t_0 * t_1 = 8(t_0+t_1-t)$, $(t_0,t_1) = 16$, $t \longleftrightarrow ab$
2B, 1A	$t_0 * t_1 = 0 = (t_0,t_1)$
3A, 1A	$t_0 * t_1 = 4t_0+4t_1+2t_2-3u$, $(t_0,t_1) = 13/2$, $u \longleftrightarrow ab$, $(u,1) = 9/2$
	$t_0 * u = 10(2t_0-t_1-t_2+u)$, $(t_0,u) = 45$, $u * u = 90u$, $(u,u) = 405$
3C, 1A	$t_0 * t_1 = t_0+t_1-t_2$, $(t_0,t_1) = 2$
4A, 2B, 1A	$t_0 * t_1 = 3t_0+3t_1+t_2+t_3-v$, $(t_0,t_1) = 4$, $v \longleftrightarrow ab$, $(v,1) = 12$
	$t_0 * v = 12(5t_0-2t_1-t_2-2t_3+v)$, $(t_0,v) = 144$, $v * v = 192v$, $(v,v) = 2304$
4B, 2A, 1A	$t_0 * t_1 = t_0+t_1-t_2-t_3+t$, $(t_0,t_1) = 2$, $t \longleftrightarrow (ab)^2$
5A, 1A	$t_0 * t_1 = \frac{1}{2}(3t_0+3t_1-t_2-t_3-t_4+w)$, $(t_0,t_1) = 3$, $w \longleftrightarrow ab$
	$t_0 * t_2 = \frac{1}{2}(3t_0+3t_2-t_4-t_1-t_3-w)$, $(t_0,t_2) = 3$, $-w \longleftrightarrow (ab)^2$
	$t_0 * w = 14(t_1-t_2-t_3+t_4+w)$, $(t_0,w) = 0$, $(w,1) = 0$
	$w * w = 350(t_0+t_1+t_2+t_3+t_4)$, $(w,w) = 3500$
6A, 3A, 2A, 1A	$t_0 * t_1 = t_0+t_1-t_2-t_3-t_4-t_5+t+u$, $(t_0,t_1) = 5/2$, $t \longleftrightarrow (ab)^3$, $u \longleftrightarrow (ab)^2$
	$t * u = 0 = (t,u)$

The complete structure of the algebra generated by t_0 and t_1 can in fact be read off from the table. Thus if ab is in class 6A, then $(ab)^2$ is in class 3A, and so $t_0 * t_2 = 4t_0+4t_2+2t_4-3u$.

In terms of the algebra, the action of a transposition can be recovered from the corresponding vector t by the formula

$$x \longrightarrow x - \frac{1}{14}\,[\,24(x,t)t + 16x * t - (x * t) * t\,]$$

The vector corresponding to a short element x_R of Q_x is $2A_R - 8X_R$, where the matrix $A_R = v_R \otimes v_R = X_R * X_R$. In particular, for $x_{ij} = y_{ij} = z_{ij}$ the vector is $4[(ii)+(jj)-(ij)_1-(ij)_2-(ij)_3]$.

The Monster is generated by N_0 together with any transposition outside N_0. We exhibit the vector t for such a transposition, from which the action of that transposition can be recovered from the above formula. Take an involution of $2Co_1$ outside $2^{12}M_{24}$ which fixes an 8-dimensional sublattice L_8. For each of the type 2 vectors v_R in L_8 (modulo 2) select one of the preimages x_R in Q_x, in such a way that the chosen preimages generate an elementary abelian group 2^8. Then $t = A - \Sigma X_R$ (summed over the corresponding X_R), where A is the matrix of the projection onto L_8.

"Presentation" $(G \times G).2 \cong \langle$  $\mid$ more relations $\rangle$

The three outermost dots are redundant. By omitting the lowest two dots we obtain generators for G. Further redundant generators may be added so as to complete the diagram to the 26-point graph whose nodes are the 13 points and 13 lines of the order 3 projective plane, joined by incidence. See page 232.

Moonshine There is an infinite sequence of characters H_n (the head characters) of G such that for each element g of G the function $T_g(z) = q^{-1} + H_1(g).q + H_2(g).q^2 + \ldots$ (where $q = \exp(2\pi i z)$) is fixed up to scalar factors by a certain group E(g) of transformations

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} : z \longrightarrow \frac{Az + B}{Cz + D}$$

In particular for g = 1 we find that E(1) is the group $PSL_2(\mathbb{Z})$ and $T_1(z) = j(z) - 744$, where j(z) is the classical elliptic modular function

$$q^{-1} + 744 + 196884q + 21493760q^2 + 864299970q^3 + 20245856256q^4 + 333202640600q^5 + \ldots .$$

The group E(g) always has the form $\Gamma_0(n|h + e_1, e_2, \ldots)$, where the parameters are integers with h dividing n and each e_i a divisor of n/h prime to $n/(he_i)$. This group is defined to consist of all matrices

$$\begin{pmatrix} ae & b/h \\ cn & de \end{pmatrix} \quad \text{of determinant } e$$

for which a, b, c, d are integers and e is one of 1, e_1, e_2, ... We abbreviate its name by omitting "|h" when h = 1, and by writing $\Gamma_0(n|h)$ or $\Gamma_0(n|h-)$ when no e_i (save 1) is present, and $\Gamma_0(n|h+)$ when all possible e_i are present. The scalar factors for elements of E(g) are :

1	for elements of the normal subgroup $\Gamma_0(nh + e_1, e_2, \ldots)$
$\exp(-2\pi i/h)$	for the element $\begin{pmatrix} 1 & 1/h \\ 0 & 1 \end{pmatrix}$
$\exp(\pm 2\pi i/h)$	for the element $\begin{pmatrix} 1 & 0 \\ n & 1 \end{pmatrix}$,

where the sign is + or − according as n/h is or is not among the e_i. These rules completely determine the subgroup F(g) of index h in $\Gamma_0(n|h+e_1, e_2, \ldots)$ that fixes $T_g(z)$ exactly. In fact $T_g(z)$ is characterized as the canonical Hauptmodul for this group F(g) – that is to say, it generates the field of all modular functions invariant under F(g) and has a series of the form $1/q + a_1 q + a_2 q^2 + \ldots$.

The symbols $n|h+e_1, e_2, \ldots$ serve as names for the conjugacy classes of G, with the slight ambiguities that g and g^{-1} have the same symbol, and that classes 27A and 27B both have symbol 27+. In this notation the "class" of g^k is $n'|h'+e_1', e_2', \ldots$ where $n' = n/(n,k)$, $h' = h/(h,k)$, and e_1', e_2', ... are the divisors of n'/h' among e_1, e_2, ...

Many properties of the elements of G and their centralizers are illuminated by this parametrization. Using $F_{n|h+e_1, e_2, \ldots}$ for the non-Abelian composition factor (when this exists) of the appropriate centralizer, we have :

F_1	F_{2+}	F_{2-}	F_{3+}	F_{3-}	$F_{3\|3}$	F_{4+}	$F_{4\|2+}$	F_{4-}	$F_{5\|2-}$	F_{5+}	F_{5-}	F_{7+}	F_{7-}
M	B	Co_1	Fi_{24}'	Suz	Th	Co_3	$F_4(2)$	$S_6(2)$	$G_2(4)$	HN	J_2	He	A_7

The names F_1, F_2, F_3, and F_5 often used for M, B, Th, and HN may be regarded as abbreviations of these F-names. The full forms can be used to exhibit the analogies between these groups.

There are replication formulae relating the various characters H_n, for instance the duplication formula

$$H_{2n}(g) = H_{n+1}(g) + \Sigma' H_i(g) H_{n-i}(g) \quad (1 \leq i \leq n/2)$$

where Σ' indicates that when n = 2m the term $H_m(g)^2$ must be replaced by $H_m^{2-}(g) = \frac{1}{2}(H_m(g)^2 - H_m(g^2))$. The duplication formula can be used to express all the H_n in terms of H_1, H_2, H_3 and H_5. The head characters H_{-1}, ... H_9 are the linear combinations of the first few irreducible characters with the coefficients

H_{-1} :	1															
H_0 :	0															
H_1 :	1	1

The Y-groups

We amplify the remarks in the section "Presentation", and in so doing provide presentations for a large number of groups. The wreath square of the Monster is a homomorphic image of the Coxeter group defined by Figure 1. Redundant generators can be added to form a graph of 26 nodes a, z_i, a_i, b_i, c_i, d_i, e_i, f_i, g_i, f ($i = 1,2,3$) in which the joins are from

a to b_i, b_j, b_k, f	z_i to a_i, c_j, c_k, e_i
a_i to z_i, b_i, f_j, f_k	b_i to a, a_i, c_i, g_i
c_i to z_j, z_k, b_i, d_i	d_i to c_i, e_i, g_j, g_k
e_i to z_i, d_i, f_i, f	f_i to a_j, a_k, e_i, g_i
g_i to b_i, d_j, d_k, f_i	f to a, e_i, e_j, e_k

where $\{i,j,k\} = \{1,2,3\}$. Abstractly, this is the incidence graph of the 13 points (z_i,b_i,d_i,f_i,f) and 13 lines (a,a_i,c_i,e_i,g_i) of the projective plane of order 3.

We define Y_{pqr} to be the subgroup of M wr 2 generated by a and

the first p terms of the sequence b_1, c_1, d_1, e_1, f_1

the first q terms of the sequence b_2, c_2, d_2, e_2, f_2

the first r terms of the sequence b_3, c_3, d_3, e_3, f_3 (see Figure 1).

Similarly, we define X_{pqr} to be the group generated by a and

the first p terms of the sequence b_1, c_1, d_1, e_1 ($p \leq 4$)

the first q terms of the sequence b_2, c_2, d_2, e_2 ($q \leq 4$)

the first r terms of the sequence b_3, a_3 ($r \leq 2$) (see Figure 2a),

and if p, $q \leq 3$ obtain X_{pqrs} by adjoining the first s terms of f, e_3 (see Figure 2b). Similarly, Q_{pqr} is generated by f_1, f_2, f_3 and

the first p terms of the sequence a_1, b_1, c_1, d_1

the first q terms of the sequence a_2, b_2, c_2, d_2

the first r terms of the sequence a_3, b_3, c_3, d_3 (see Figure 3).

The structures of these groups, and multiple covers of certain of them, are tabulated on the next page. The intersection of Y_{pqr}, $X_{pqr(s)}$, Q_{pqr} with M x M is a subgroup of index 2 which projects isomorphically into M in all cases of the table except

Y_{444} (image = M) $\quad X_{2222}$ (image = $2^{10+16}.O_9(2)$) $\quad X_{3222}$ (image = $2^{10+16}.O_{10}^{+}(2)$)

We have

$Y_{5qr} = Y_{4qr}$ if $q > 1$, $r > 0$ $\qquad Q_{4qr} = Q_{3qr} = Y_{3,q+1,r+1}$ if $q > 0$

$X_{pqr} = Y_{pqr}$ if $r < 2$ $\qquad X_{442} = X_{432}$ $\qquad X_{33rs} = X_{32rs}$ if r, $s > 0$

<u>Defining relations.</u> We define $f_{ij} = (ab_ib_jb_kc_ic_jd_i)^9$, whenever $\{i,j,k\} = \{1,2,3\}$. We conjecture that M wr 2 is the abstract group defined by the Coxeter relations of Y_{555} (Figure 1) together with

$f_1 = f_{12}$ or f_{13}, $\quad f_2 = f_{23}$ or f_{21}, $\quad f_3 = f_{31}$ or f_{32}.

It is known that the eight alternatives here are mutually equivalent, and define the same group as the Coxeter relations of Y_{444} together with the relation $S = 1$ of the table, when the above relations are used to define the f_i. With the further definitions

$$z_i = f_i(ab_ib_jb_kc_id_i)^5 \qquad f = f_i(c_id_ib_jc_jd_jz_k)^5$$

$$a_i = f_je_jd_jc_jb_jab_kc_kd_ke_kf_k \qquad g_i = c_i(ab_jc_jc_ke_if)^5$$

these relations imply all the Coxeter relations of the projective plane.

The "relations" column gives relations that complete (or conjecturally complete) the Coxeter relations to a presentation in the other cases. Using also the information in the "centre" column of the table one can derive presentations for many groups. Thus the Coxeter relations of Y_{332} together with

$f_{12}=f_{13}$, $f_{21}=f_{23}$;	$f_{12}=f_{13}$, $f_{21}=1$;	$f_{12}=f_{21}=1$;	$S=1$;	$f_{12}=f_{21}=S=1$

are presentations for the respective groups

$(3\times 2^2)Fi_{22}$;	$6Fi_{22}$;	$3Fi_{22}$;	2^2Fi_{22};	Fi_{22}.

Partitions and the classes and characters of S_n

The table gives the usual correspondences between partitions and the classes and characters of S_n. In the table,

N is the largest part of the partition,

m+ refers to the m'th printed character of the ATLAS table,

m− to its associated character, and

m,M to the sum of the m'th and M'th ATLAS characters of A_n.

The characters of the Schur double covers are also indexed by partitions. More precisely, a partition of n into distinct parts refers either to two characters of $2A_n$ that fuse in $2S_n$, or to two characters of $2S_n$ that agree on $2A_n$. The partition indicates the S_n image of the classes on which the two characters differ.

The following provides enough information to define the Schur double covers $2A_n$, 2^+S_n and 2^-S_n. The preimages in $2^{\pm}S_n$ of the permutation

$$(abc\ldots)(ghi\ldots)(pqr\ldots)\ldots$$

are $\pm\theta$, where

$$\theta = [abc\ldots][ghi\ldots][pqr\ldots]\ldots$$

and we have

$$[a_1a_2a_3\ldots a_k] = [a_1a_2][a_1a_3]\ldots[a_1a_k].$$

If ϕ is either preimage of the permutation taking

$$a \longrightarrow A,\ b \longrightarrow B,\ c \longrightarrow C,\ \ldots$$

then we have

$$\phi^{-1}\theta\phi = \pm\ [ABC\ldots][GHI\ldots][PQR\ldots]\ldots$$

where the sign is − just when the images of θ and ϕ are both odd permutations.

We have

$$[a_1a_2\ldots a_k]^k = \begin{cases} +1 & +1 & +1 & -1 & -1 & -1 & -1 & +1 & \text{in } 2^+S_n \\ +1 & +1 & -1 & +1 & -1 & -1 & +1 & -1 & \text{in } 2^-S_n \end{cases}$$

$$\text{according as} \qquad k \equiv 0 \quad 1 \quad 2 \quad 3 \quad 4 \quad 5 \quad 6 \quad 7 \pmod 8$$

Involvement of sporadic groups in one another

For each sporadic simple group G, we ask which smaller sporadic groups are involved in G (that is, are quotients of subgroups of G)? In the table the entry in the row for G and the column for S is

- \+ if S is involved in G
- \- if S is not involved in G
- ? if we don't know ($S \cong J_1$, $G \cong M$)

If J_1 is involved in M, then it must be as a maximal subgroup, with conjugacy classes 1A, 2B, 3C, 5B, 6F, 7B, 10E, 11A, 15D, 19A.

Bibliography

Our main bibliography refers only to the sporadic groups. We add here a few works chosen because they deal with most of the major families of simple groups. Many of them contain extensive bibliographies.

A.Reifart, A 2-local characterization of the simple groups M(24)', ·1 and J_4, J. Algebra 50 (1978) 213-227

R.M.Stafford, A characterization of Janko's new simple group J_4, Notices Amer. Math. Soc. 25 (1978) A-423

R.M.Stafford, A characterization of Janko's new simple group J_4 by centralizers of elements of order three, J. Algebra 57 (1979) 555-566

G.Stroth, An odd characterization of J_4, Israel J. Math. 31 (1978) 189-192

Fischer group Fi_{24}

S.L.Davis and R.Solomon, Some sporadic characterizations, Comm. Algebra 9 (1981) 1725-1742

B.Fischer, Finite groups generated by 3-transpositions, Preprint, Warwick

S.P.Norton, F and other simple groups, Ph.D. thesis, Cambridge, 1975

S.P.Norton, Transposition algebras and the group F_{24}, Preprint, Cambridge

D.Parrott, Characterizations of the Fischer groups, Trans. Amer. Math. Soc. 265 (1981) 303-347

A.Reifart, Some simple groups related to M_{24}, J. Algebra 45 (1977) 199-209

A.Reifart, A 2-local characterization of the simple groups M(24)', ·1 and J_4, J. Algebra 50 (1978) 213-227

Baby monster group B

J.Bierbrauer, A characterization of the "Baby monster" group F_2, including a note on ${}^2E_6(2)$, J. Algebra 56 (1979) 384-395

D.G.Higman, A monomial character of Fischer's Baby Monster, in "Proceeding of the Conference on Finite Groups" (W.R.Scott and F.Gross, eds.) pp. 277-284, Academic Press, 1976

O.Kroll and P.Landrock, The characters of some 2-blocks of the Baby Monster, its covering group, and the Monster, Comm. Algebra 6 (1978) 1893-1921

J.S.Leon, On the irreducible characters of a simple group of order $2^{41}.3^{13}.5^6.7^2.11.13.17.19.23.31.47$, in "Proceedings of the Conference on Finite Groups" (W.R.Scott and F.Gross, eds.), pp. 285-299, Academic Press, 1976

J.S.Leon and C.C.Sims, The existence and uniqueness of a simple group generated by {3,4}-transpositions, Bull. Amer. Math. Soc. 83 (1977) 1039-1040

C.C.Sims, How to construct a Baby Monster, in "Finite Simple Groups II" (M.J.Collins, ed.), pp. 339-345, Academic Press, 1980

G.Stroth, A characterization of Fischer's sporadic group of order $2^{41}.3^{13}.5^6.7^2.11.13.17.19.23.31.47$, J. Algebra 40 (1976) 499-531

Monster group M

J.H.Conway, Monsters and moonshine, Math. Intellingencer 2 (1979/80) 165-171

J.H.Conway, A simplified construction for the Fischer-Griess Monster group, Invent. Math., to appear

J.H.Conway and S.P.Norton, Monstrous moonshine, Bull. London Math. Soc. 11 (1979) 308-339

S.L.Davis and R.Solomon, Some sporadic characterizations, Comm. Algebra 9 (1981) 1725-1742

P.Fong, Characters arising in the Monster-modular connection, in "The Santa Cruz conference on finite groups" (Cooperstein and Mason, eds.), pp. 557-559, Amer. Math. Soc., 1980

I.Frenkel, J.Lepowsky and A.Meurman, A natural representation of the Fischer-Griess Monster with the modular function J as character, Preprint, Berkeley, 1984

R.L.Griess, The structure of the "Monster" simple group, in "Proceedings of the Conference on Finite Groups" (W.R.Scott and F.Gross, eds.), pp. 113-118, Academic Press, 1976

R.L.Griess, A construction of F_1 as automorphisms of a 196,883-dimensional algebra, Proc. Nat. Acad. Sci. USA 78 (1981) 689-691

R.L.Griess, The Friendly Giant, Invent. Math. 69 (1982) 1-102

R.L.Griess, The monster and its non-associative algebra, in "Proceedings of the Montreal Conference on Group Theory (1982)", (J.McKay, ed.)

V.G.Kac, A remark on the Conway-Norton conjecture about the "Monster" simple group, Proc. Nat. Acad. Sci. USA 77 (1980) 5048-5049

O.Kroll, The characters of a non-principal 2-block of the Monster F_1 (?), Preprint Ser. Math. Inst. Aarhus Univ. 31 (1977)

O.Kroll and P.Landrock, The characters of some 2-blocks of the Baby Monster, its covering group, and the Monster, Comm. Algebra 6 (1978) 1893-1921

S.P.Norton, The uniqueness of the Fischer-Griess Monster, in "Proceedings of the Montreal Conference on Finite Group Theory (1982)", (J.McKay, ed.)

J.G.Thompson, Uniqueness of the Fischer-Griess Monster, Bull. London Math. Soc. 11 (1979) 340-346

J.G.Thompson, Finite groups and modular functions, Bull. London Math. Soc. 11 (1979) 347-351

J.G.Thompson, Some numerology between the Fischer-Griess Monster and the elliptic modular function, Bull. London Math. Soc. 11 (1979) 352-353

J.Tits, Le Monstre, Seminaire Bourbaki (1983/84), No. 620

J.Tits, On R.Griess' "Friendly Giant", Invent. Math., to appear

T. van Trung, On the "Monster" simple group, J. Algebra 60 (1979) 559-562
